Nice plot. Kinda looks like you'll need a rotator. The -3dB
beamwidth varies from 54 to 95 degrees. At best, 3 antennas will
cover 3*95 = 285 degrees. At worst, 3*54 = 162 degrees.

>Was considering 3 antennae with wide reception angles pointed generally at
>45, 140, 310 deg. Only 3 are LOS (15, 18, 33)

What are the ranges and approximate signal strengths? Looks like 18
and 33 can be covered with one antenna pointed at about 250 degrees. A
second antenna at 45 degrees *MIGHT* catch the largest number of
channels. However, there's no optimum location for a 3rd antenna to
catch all the remaining stations. You'll probably have to pick and
choose among the relatively strong ones and take what you can get.
With a UHF only antenna, stations 2-13 are problematic (or
impossible). If you're going to run multiple antennas, you'll
probably need an antenna switch, 3 tower mounted amplifiers, and 3
coax cable runs. If you try to combine then with a power splitter,
you'll get interaction between antennas and an ugly and unpredictable
pattern.

With an indoor antenna of any sorts, which ones can you receive
(including the weak ones)? With only 4dBi of antenna gain, I don't
think you'll be able to dig the ones you can't receive out of the
noise.

>Pretty flat terrain, no tall structures nearby . Top of the mast: 14 ft. agl.

They let you have a 14 ft mast and you're worried about the antenna
police? Might as well go for broke. Install a real yagi antenna,
tower mounted amplifier, and rotator. For the tower amp, I recommend
a Channel Master 7777.
<http://www.channelmasterintl.com/amplifiers.html>
For an antenna, whatever you can find. The bigger and uglier the
anenna, the better it works. See specs at:
<http://www.hdtvprimer.com/ANTENNAS/comparing.html>

If you're not sure, buy just one antenna, hang it out the window on a
broom stick, and see what it does. If you're close, continue with

your proposed ideas. If it looks hopeless, give up before you burn
any more money.

Hi Bruce,

Well put to the point above, but for my money Stephan probably
couldn't follow through to a numerical solution. Retirement appears
to have him drifting through newsgroups; gracing us all with the
enlightening questions of an acolyte pondering the eternal mysteries.
If he were a monk begging for rice, he would starve at this rate.

Art, on the other hand, is like a monk with a gallon of gas....

I would suggest it came about because cable operators have a strong lobby and wanted to be deregulated. The FCC was reluctant to do so as long as many apartment- and condo-dwellers had no choice but to subscribe to cable. By ensuring these people have access to OTA TV you ensure (at least in theory) that if deregulated cable rates get too high, one can switch to OTA or satellite.

==========

Either way, Elmo is indeed correct.

Hi, Gordon,

I recall when you introduced your neat handiwork to the group. I meant to ask a question:

Did you ever try connecting each of the antennas' twin lead to its own separate balun and combine the 75-ohm sides of the baluns into a single coax? A passive splitter, connected backwards, performs this function nicely.

I ask because, as you have your antenna wired (two antennas in parallel to a single balun) looks like an impedance mismatch; the balun wants a 300-ohm connection to the two screws and two 300-ohm antennas at the same time would be 150-ohms. I think you previously said you are not a techie, so forgive me if I'm using terms you don't know.

Not being one to argue with success, if you tried it and it wasn't any better, then more power to you. Rock on!

"Sal"

PS: For my fellow techies: Yes, I realize the 300-ohm figure for a bowtie is nominal and the actual impedance will differ from that figure. Paralleling the two antennas could be superior.

No, I didn't think to try that. I could give it a shot, I have all
the necessary parts. I am concerned about loss, and thought that
the extra hardware would introduce too much extra loss.

I'm following you.

Hmmm... Yes. I can see how there could be a mismatch. But I
thought that only applied to simple things like resistance in DC
and AC circuits. RF is not one of my forte`s.

Anyway, I was trying to mimic the Channelmaster two and 4 bay
bowtie designs, that seem to have a 300 ohm feed.

Maybe someone could explain that.

>

Well, I got an improvement, probably in spite of myself. The
setup gives better signal strength, and is less suseptable to
interfearence (people walking aroung the room) than just a
single bowtie.

Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

"1861 - Maxwell publishes a mechanical model of the electromagnetic field. Magnetic fields correspond to rotating vortices with idle wheels between them and electric fields correspond to elastic displacements, hence displacement currents. The equation for now becomes , where is the total current, conduction plus displacement, and is conserved: . This addition completes Maxwell's equations and it is now easy for him to derive the wave equation exactly as done in our textbooks on electromagnetism and to note that the speed of wave propagation was close to the measured speed of light. Maxwell writes, ``We can scarcely avoid the inference that light in the transverse undulations of the same medium which is the cause of electric and magnetic phenomena.'' Thomson, on the other hand, says of the displacement current, ``(it is a) curious and ingenious, but not wholly tenable hypothesis.''

"1864 - Maxwell reads a memoir before the Royal Society in which the mechanical model is stripped away and just the equations remain. He also discusses the vector and scalar potentials, using the Coulomb gauge. He attributes physical significance to both of these potentials. He wants to present the predictions of his theory on the subjects of reflection and refraction, but the requirements of his mechanical model keep him from finding the correct boundary conditions, so he never does this calculation."
From: http://maxwell.byu.edu/~spencerr/phys442/node4.html

Try understand: "the mechanical model is stripped away and just the equations remain."

Now engineers are using model with compressible, massive electrons. The equations are used by teacher to teach the math.

According to Maxwell model the radio waves are transversal. Are such in your radio reality?

You are right when you are writing about antennas and me. I hope that my
"enlightening questions" make that you (engineering people) start to press
on teachers to stop teaching about Maxwell model (transverse waves).

Your (engineering people) model is O.K. but it is quite different from the Maxwell model. This is the reason that Art can wrote: " "For your information you have never built an antenna that conforms in its entirety to Maxwell';s laws thus you cannot possibly understand radiation as presented by Maxwell."

Art Unwin wrote:
> Does that mean that a radiator reduces mass with use
> because the electrons orbiting around the atom are losing mass?

Since mass and energy are equivalent, I suppose the mass
of the radiator increases with increasing power input.
The increase in mass can be calculated but the average
ham has no way of measuring the increase. No need to
worry about the tower falling down due to additional
mass from energized electrons. :-)

The antenna is charged up to a certain energy level
during the key-down transient state. Since the energy
content of the antenna cannot increase forever, it must lose
energy as photonic radiation and/or as heat during steady-state.

Free electrons in a conductor travel at much less than the
speed of light. Photons are emitted from the electrons at
the speed of light. A quote from:

http://c2.com/cgi/wiki?SpeedOfElectrons

"For example, for a copper wire of radius 1 mm carrying
a steady current of 10 Amps, the drift velocity is only
about 0.024 cm/sec!" i.e. about 0.01 inch/second. Ignoring
random movements, the electrons at our RF transmitter never
reach the antenna. At 10 MHz, the electrons move less than
0.000000001 inch during a 100 nS cycle involving a 100 watt
transmitter, i.e. they mostly oscillate in place.

However, other electrons, traveling at a large percentage
of the speed of light, are quite massive as observed in
particle accelerators and radioactive decay.

A mismatch can cause ghosting in an analog TV.
What does ghosting do to a digital TV signal?

If its bad enough it will wreck the reception. But the latest
processors can tolerate multipath that is only 1 db down.

They are getting better as they try to debug HDTV for mobile reception.

Hi S,
Interesting to read what you say as there are many similarities to my
antenna work.
A small addition with respect to light formation. Displacement current
is the action required of three dimensional equilibrium which is why I
often point to the helicopter as an example,
same thing goes for a gyroscope or the Sedgway scooter. It is this
circular motion that holds to the understanding of light since this
provides the spin of a particle such that it has straight line
trajectory. The frequency of circular motion is what changes when the
particle
enters a medium that is resistive where the spin increases to maintain
the straight line projection. The energy for this increase in spin is
the latent energy that is removed from
the particles potential energy similar to latent heat with liquids.
Thus energy is conserved
by the increase in spin which is analogous to change in frequency!
This change in frequency brings the particle into the area of color ,
light and X rays ie higher frequencies and the latent energy shows up

as light until there is no more energy left and the particle has vaporized such that light progresses to invisiblity. This being similar to the effects shown of a meteorite as it comes into contact with the resistive environment of Earth.
With respect to radiation from the ends of a radiator. This can only happen when the radiator is a fraction of a wavelength when the law of equilibrium is violated. The accellaration of charge at the end is without spin applied and tho there is radiation it becomes non directional and unable to overcome the gravitational force and falls within a short distance.

It puts 'ripples' into the passband. The ripples happen because of
phase cancelations. The ATI HDTV Wonder cards can handle variations to
around 8-10 dB. After that it just freezes up.

Near the bottom of the page in the link there is an example of the
ATSC spectrum. Add random dips into it.

Cecil
The above is confusing unbound particles with bound particles both of
which can be considered a particle but only one has motion ie both
kinetic and potential energies where as the static partical only has
potential energy where the potential energy of both is equal.
The bound particle is in circular motion around a point source ala the
atom,

this collection of particles are in a state of three dimensional equilibrium in relation to other similar clusters of particles which provides a mass that in total is in static equilibrium
within its own boundary. If you supply energy to this mass in equilibrium the frequency of rotation of particles increases and could increase to the point of the frequency of light where, if it continues, could become vaporised such that we now have a new medium consisting of partial pressures of gasses.
The other particle when in equilibrium is at rest i.e unbound as has lost a lot of potential energy in its voyage from the Sun ala the sun spots. Energy is and can be added via electric energy where a displacement current is formed such that the resting particle receives the same amount of energy that it lost in its travels thru the universe. The only difference between the two particles is the boundaries in which they are seen to be enclosed in equilibrium ie same potential energy but in different scalar form. (two dimensional compared to three dimensional equilibrium). I can only assume that what you refer as a photon is the separation of latent energy with respect to potential energy ie a separation of the energies associated with the particle with spin

Your worst nightmare. From 10 years ago:
<http://www.businessweek.com/bwdaily/dnflash/aug1999/nf90826b.htm>
(Note the sales predictions, which were totally wrong).
All DTV chipsets now have ghost elimination circuitry, which does a
good job of reducing multipath problems. There's a spec for it but
I'm too lazy to look. Here's the patent:
<http://www.google.com/patents?id=XNp3AAAAEBAJ&dq=7038732>
with references to others in citations. I won't pretend to understand
how it works.

Although it may be possible for an electron to be
"at rest", that concept violates the uncertainty
principle. Free electrons jump from atom to atom
but they are never in a fixed position until they
are measured in that fixed position in which case,
they give up their velocity/momentum as an unknown.

Whoever first said, "One cannot have one's cake
and eat it too." apparently understood the
uncertainty principle. :-)

That are speculations only. Everybody know that at the end of an antenna the
high voltage appears. It means that density of electrons change. The
movements must be bigger.

There is no "velocity " inside a radiator. There is a current flow on
the surface and when there is no skin effect at the ends of a radiator
that is not in equilibrium then the charge is free to flow off the
ends but without contra or levitating spin just like a helicopter when
one of its rotors comes to a stop. The rotor that is still turning
takes a spin increase like a motor start up with no load until a spark
is realised when the spin rotates at a particular frequency

I have just made a larger than usual antenna that radiates well below
the broadcast band so I may study generated radiation patterns. The
antenna
is on a structure that rotates as well as a tipping action, all about
4 feet above the ground. Initially I will just listen to signal
variences when aim and tilt is in the best position. I recognise that
I may have to put a digital meter across the S meter terminals
together with a holding capacitor but for the moment I will be guided
by the S meter. On the upper frequencies I will hook up to a TV for a
visual. SWR readings will be initially recorded
across all frequencies in the horizontal position to be used as a
datum
which certainly be required as shielding is added in the near future.
Comments?

In countries using COFDM (DVB-T), the symbol time is about 1000 us
(8k) or 250 us (2k), so in the worst case with minimal guard
intervals, you can still use mismatched coaxial cables longer than 1
km without problems :-).

With ATSC 8VSB it depends how well the equalizer is capable of
detecting the characteristics of the radio and coaxial path with a
known signal pattern.

29. SWR variation with feedline length

Newsgroup: rec.radio.amateur.antenna
Date: 2009-06-01 20:50:52 UTC
From: Antonio Vernucci <vernucci@tin.it>
Message-ID: <4a243f2c$0$1117$4fafbaef@reader3.news.tin.it>
Source record: 15141

Along several decades of radio hamming on the HF bands, I noted that the measured SWR of all the antennas I have mounted (Yagis, dipoles) slightly varies when the feedline length is changed by several meters. For 100W of forward power, the reflected power could vary somewhat, e.g. from 2W to 5W or so, measured on a Bird wattmeter. This behavior would seeem to deny the theory, according to which SWR is independent of feedline length (as long as the cable attenuation remains constant).

Clearly the measured SWR change cannot be due to the change in the feedline attenuation as, at HF, adding or cutting a few meters of cable would yield a very small change in attenuation and hence a negligible impact on measured SWR.

Reading here and there, the most common theory explaining such phenomenon is that, in presence of RF on the coaxial cable braid, the SWR meter reading is influenced by the feedline length. I am not too convinced of that explanation, also because I have invariably experienced the measured SWR variation phenomenon with all antenna I have had, and I never had hot braid problems.

At that regard I got an idea that could explain the phenomenon, at least part of it.

Reading coaxial cable data sheet, I noted that manufacturers typically give a small tolerance on cable impedance (2 to 3 ohm). Let us then assume that the feedline cable has a 53-ohm impedance, whilst the Bird wattmeter is 50 ohm sharp.

If the 53-ohm cable is terminated on an e.g. 75-ohm (purely resistive) antenna, the real SWR on the line would be 75/53=1.41 independently of feedline length (if the attenuation variation with length is neglected). But the impedance seen by the wattmeter obviously varies with the feedline length, and it can be easily calculated that the seen impedance range results in an apparent SWR, on the 50-ohm wattneter, reading that varies from a maximum of 1.5 (when feedline length is an even multiple of half wavelenght) down to a minimum of 1.33 (when feedline length is an odd multiple of wavelenght quarters). For 100W of forward power, the reflected power varies from about 4W down to about 2W.

Repeating the exercise with an e.g. 85-ohm load, the apparent SWR measured on the 50-ohm wattmeter would vary from 1.7 down to 1.51 (reflected power varying from 7W down to 4W).

You can get easily convinced that such variation is only due to the assumed 3-ohm difference in cable impedance.

With older cables having a nominal 52-ohm impedance, instead of 50, the situation could get even more evident.

Any comment would be appreciated.

Actually, the fact that they try to bunch up at the ends
of a standing wave antenna during part of the cycle implies
that they slow to a stop thus repelling other electrons and
have nowhere else to go except to reverse direction during
the next 1/2 cycle.

The Bird actually measures a combination of capacitive coupled voltage and
inductively coupled current. There is a app note on the Bird website.
Find: "Straight Talk About Directivity".

If the characteristic impedance of the feedline differs from
the characteristic impedance of the calibrated SWR meter,
the indicated SWR will vary with length of feedline.

If the feedline is lossy, the transmitted signal SWR will
decrease between the antenna and the transmitter. All
feedlines have a certain amount of loss.

If common-mode current is present on the SWR meter case,
the SWR reading will vary because the meter has no fixed
ground reference.

ah, you believe 'and so on'?? the 'so on' means the changing electric field
creates a magnetic field... both conditions are required for electromagnetic
propagation. without the time varying displacement current there would be
no propagation. so yes, you can create a magnetic field from the time
varying electric field.

the maxwell equations completely describe radiation from an antenna, so all
antennas, even arts, 'conform' to the maxwell equations.

David
I am not ignoring you. I have responded to lots and lots of your questions but you do not respond in kind. It started years ago with a time varying current being applied to Gass's law of Statics and you have rebelled to everything said since then, and not once have you explained the definitive reasons as to why you reject all. As I have said many times, I do not work for you. I am not in your employ. As for Maxwell's equations, he accounted for all the forces involved in the generation of radiation within the boundary of equilibrium. A Yagi is not in equilibrium so the difference is chalk and cheese. Both radiate ofcourse tho the sizes do differ as does the bandwidth as well as the TOA but the point I am making is that if your radiation assembly is not in equilibrium you are not following the tenents of Maxwell. A very simple distinction as is the accelleration of the charge contained by a departing particle compared to a wave of some sort or energy content that is capable of a straight line projection without interference from gravitational forces or progressions to the existance of light, X rays, e.t.c.
Have a very happy day and sleep tight and don't get your knickers in a twist
Regards
Art

38. Re: SWR variation with feedline length

Newsgroup: rec.radio.amateur.antenna
Date: 2009-06-02 00:01:47 UTC

Source record: 15062

It's important to know and keep in mind that the SWR meter doesn't
actually measure the SWR on the feedline. So its reading doesn't prove
or disprove anything about how the SWR on a feedline changes with length.

What the meter effectively measures is the impedance seen at that point.
It's calibrated in such a way that if it's connected to a transmission
line of exactly 50 ohms impedance, the indicated SWR will be the SWR on
the line. Otherwise, the indicated SWR won't be the actual line SWR.

There are at least three things which can cause an indicated SWR
variation with line length:

1. The feedline Z0 isn't exactly 50 ohms. The Z0 of coax easily varies
+/- 5 ohms from nominal, and sometimes closer to +/- 10 -- it's seldom
exactly 50. If you connect a perfect 50 ohm load to your transmitter via
a 45 ohm line, the impedance seen by the transmitter will change with
line length. Consequently, the SWR meter reading will also change. The
actual SWR on the line will not, except as dictated by loss, described next.

2. The feedline has loss. The SWR will improve as the line becomes
longer due to line loss. If the line is long enough to be very lossy,
the transmitter will see nearly the line's Z0 regardless of what load is
connected to the other end. The actual SWR on the line will be greatest
at the load, decreasing as you get farther away.

3. There is current on the outside of the coax shield (common mode
current). When this happens, the feedline becomes part of the antenna.
Consequently, changing the feedline length actually changes the
effective antenna length, which in turn changes the feedpoint impedance.

Hi Antonio,

Yes, this is the accepted wisdom.

>Clearly the measured SWR change cannot be due to the change in the feedline
>attenuation as, at HF, adding or cutting a few meters of cable would yield a
>very small change in attenuation and hence a negligible impact on measured SWR.

A good point.

>Reading here and there, the most common theory explaining such phenomenon is
>that, in presence of RF on the coaxial cable braid, the SWR meter reading is
>influenced by the feedline length.

This, too, is accepted wisdom.

>I am not too convinced of that explanation,
>also because I have invariably experienced the measured SWR variation phenomenon
>with all antenna I have had, and I never had hot braid problems.

You ARE describing a hot braid problem. At the slight shift of 3W out
of 100W, it is a small problem by the same degree (nothing you would
notice by other indications).

>At that regard I got an idea that could explain the phenomenon, at least part of
>it.

Well, I am going to skip that quote to cut to the chase. What you
describe is called mismatch uncertainty. It exists in a cable that
has a nominal Z that matches neither the load nor the source.
Depending upon the amount of mismatch at each end, you have a zone of
confusion between those ends that will result in as many different
readings as you have insertion points to measure at. As most modern
transmitters have a source Z of 30 to 70 Ohms, you might note a very,
very small perturbation when the other end of ANY line is mismatched -
but I doubt it. To provoke this condition into revealing readings
that are significantly beyond the range of error requires mismatches

at both ends on the order of 3:1. You don't describe that.

More likely your problem is Common Mode currents - what you call hot braid. One test is to use a snap-on choke and slide it along the line and note if the SWR meter reading moves in concert with the hand motion (or the reading simply shifts by the addition of the choke).

Hello Antonio,

In my opinion (when dealing with actual antennas) it can be:

1. your coaxial cable is part of the antenna (common mode current). Changing the length, changes the common mode impedance. You can rule this out by sliding some large ferrites along the cable close to the VSWR meter, or change the grounding a bit and watch the difference (if present).

2. your bridge inside the VSWR meter is not perfect. You can check this by connecting known impedances (for example 56 Ohms resistor and a 44.6 Ohms resistor and 100 ohms versus 25 Ohms).

3. The cables you are using are not exactly 50 Ohms. I think your analysis is right. When you have cable with slightly different Z0, readings depend on length. Of course when you extend with a good 50 ohms cable (directly connected to the meter), the reading should not change. I did the math also and found also VSWR=1.7 and VSWR=1.51 for 85 ohms load connected to cable with Z0=53 Ohms. I didn't expect such difference for just 3 ohms deviation from 50 Ohm.

4. Harmonics in the final amplifier (I hope that is not the reason).

Best regards,

Not up to your usual standards, but it sounds like you made an antenna
that is much much too small and won't see any directionality unluss it's
operating (too put it simple for you) as a magnetic antenna.

You'll notice if it works 90 degrees from what you'd expect.

I think it is convincing too.
Science is wonderfull when you connect every thing together and a
picture becomes visible. Same goes for cross word puzzles. My UK born
son was educated in American schools starting with Montessori. He now
earns a good living at La Hoya so education in America is not the
culprit for your observations. Maybe you are over estimating your own
abilities when comparing. However, now is your chance to correct the
"wrongness" that I quote.
I am all ears. After all you have won competitions with your antenna
designed but garnished from the many text books. Note that David is
now comfortable in giving displacement current some credit for
propagation so he must be younger than I thought
according to your interpretations. Now how does a wave traverse the
Earth without
collapsing? What is the connection to light? Does the "belts" that
surround the World act as breakwaters which accounts for the rainy
seasons?I suspect that it is explained in the books somewhere except
that somebody removed a page! Actually, I dreamt most of it and also
made antennas following the small print, and they worked ! Well at
least in my dreams. It must be a miracle. What do you think?

There is a very good possibility that your analysis is correct. I see the same effect, and in fact, it's of particular concern to me right now, because I'm putting what effectively is an SWR meter into production, and it's important that we have a test setup that accurately measures the performance. I've been specifically concerned that the test setup, as currently configured, may have trouble because the connecting cables may not be close enough to 50 ohms.

As others have said, IF there is a problem with RF on the outside of the line, any variation in observed SWR is most likely because the change in line length has changed the load the other end of the coax is seeing, NOT because the meter is directly responding to the "outside" RF. The meter measures transmission line current and transmission line voltage, and the line itself is all the reference it needs to do that. Direct response to RF on the outside of the line could result from poor construction of the meter, but I wouldn't expect that from a Bird.

One other possibility that I haven't seen mentioned, too, is that the impedance of the line is not constant along its length. With line of good construction that hasn't been abused, the variation should be small. You can detect it by running a network analyzer sweep of just the line, across a broad frequency range. But a line with polyethylene dielectric (and especially one with foam polyethylene) that's gotten too hot--perhaps because of high power at high SWR--can have the center conductor go "off-center" and change the impedance.

If the effect you are seeing is the result of a line that's not quite the same impedance that the meter is calibrated to (which itself may be noticably different from 50 ohms), you could plot the change in indicated SWR as a function of line length and see it vary in a smooth and predictable manner. Most likely, though, what you're seeing is the sum of several effects, and the variation in indicated SWR or reflected power may not be all that smooth. Very often when I expect to see a nice smooth spiral centered on one point on my network analyzer's Smith chart display, what I see is a spiral that follows along some arc, because of various imperfections. (Sometimes it's fun to try to figure out just what the imperfections are...)

Cheers,
Tom

Hi, Roy

yes, that is the reason why I was talking of "apparent" or "measured" SWR,
whilst the real SWR does not vary with line length.

> 1. The feedline Z0 isn't exactly 50 ohms. The Z0 of coax easily varies +/- 5
> ohms from nominal, and sometimes closer to +/- 10 -- it's seldom exactly 50.

I would say that in case no. 1 the meter measures an apparent SWR, whilst in
case no. 2 it measures the real SWR existing at the measurement point. I am not
sure what it measures in case no. 3

Regards.

Hi Cecil.

in the first case the meter measures an apparent SWR, whilst in the second case
it measures the real SWR (occuring at the measurement point).

For the third case, I am unable to figure out whether the meter reads an
apparent or the real SWR.

> had raised.

I wrote some notes on the operation of the Bruene type VSWR meter at
http://www.vk1od.net/transmissionline/VSWR/VSWRMeter.htm . The Bird 43 is
not a Bruene type meter, but a similar derivation could be done, and for
all practical purposes, the explanation applies.

Keep in mind that the usual practice of calibrating a VSWR meter is to
adjust it for nil reflected indication with a load of 50+j0. Without
arguing the tolerances implications, its indicated VSWR can only be
applied exactly to an adjacent low loss line with Zo=50+j0... which you
do not have, so you must expect some error in the measurements.

If you read the article I gave earlier, you will see the plots of VSWR
along a specification RG58C/U line with a 50+j0 +/-0% load. Those are the
indications you would expect of a *perfectly* calibrated Bird 43 on
RG58C/U exactly meeting the specification from which the RLGC parameters
were derived.

These are very small effects, but they exist.

Layer on top of that cable tolerance and you have more variation.

But, if you are making measurements using an antenna as a load, I
respectfully submit you probably are not in a sound position to assert
that there is zero common mode current effect.

As a brain teaser, think of the situation in which rho, the magnitude of
the voltage reflection coefficient Gamma could be greater than 1. Of
course many think they have proven that cannot happen my citing
measurements made with a Bird 43... but can it capture what is happening?

Owen

Our Wullenweber at Hanza had two concentric rings of antennas, the high band and the low band. And it did have a phasing system to form a beam. The pattern was very sharp.

Oddly, most of what shows in a Wullenweber photograph isn't antennas, at all, but the passive screens that give the array its characteristic of seeing just off to one side. In some photos the ring of monopole antennas can be tough to spot.

Unfortunately for this discussion, I didn't work in any of the DF shops. I was in the Comm Shop -- crypto, TTY, telephone & mux maintenance. What I learned about DF was just picked up along the way.

Not a fatter wire with twice the current?

Recall the colinear J-pole, The two currents are stacked and fed in phase by means of the phasing section. Yes, I realize the currents in the Slim Jim would appear to cancel.

I'm going to have to build one of these and see what it does. I have a lot of twinlead and I have a precision RF generator. I always wanted my own antenna range; tomorrow's the day. Maybe Tuesday.

All time I am writing about the original Hertz apparatus. See:
(http://people.seas.harvard.edu/~jones/cscie129/nu_lectures/lecture6/hertz/Hertz_exp.html

There the ends of the dipole are named "capacitor plates". In the center of
the dipole the sparks jump. The question is which part of the Hertz
apparatus radiate? The capacitor plates (voltage pulses) or the sparks (AC
current).

AC current create the transverse waves. The capacitor plates (or balls)
longitudinal waves.
What are the radio waves: transversal or longitudinal?

Surely this sounds about right for a Bird 43. Assuming a directivity for the meter of 30dB and an swr of 1.4:1 this would give a possible indicated return loss of between about 13 to 16dB depending on the relative phases of the forward and reflected signals. So moving the meter would give an indicated reflected power anywhere in the 2 to 5W range.

>Hi S,
>Interesting to read what you say as there are many similarities to my antenna work.

Yes. But I do not try to work out a new theory. For me the 200 years old "acoustic analogy" is enough.

>A small addition with respect to light formation. Displacement current

Displacement current is necessary in the model with electricity in form of the incompressible fluid. Incompressible fluid is a history.

>is the action required of three dimensional equilibrium which is why I often point to the helicopter as an example,
same thing goes for a gyroscope or the Sedgway scooter. It is this circular motion that holds to the understanding of light since this provides the spin of a particle such that it has straight line trajectory.

Straight line trajectory is normal phnomenon at the high frequences. The ultrasonic waves are like radii (see sonar)

>The frequency of circular motion is what changes when the particle enters a medium that is resistive where the spin increases to maintain
the straight line projection. The energy for this increase in spin is the latent energy that is removed from
the particles potential energy similar to latent heat with liquids. Thus energy is conserved by the increase in spin which is analogous to change in frequency!
This change in frequency brings the particle into the area of color , light and X rays ie higher frequencies and the latent energy shows up as light until there is no more energy left and the particle has vaporized such that light progresses to invisiblity. This being similar to the effects shown of a meteorite as it comes into contact with the resistive environment of Earth.

Each new theory is very difficult for me. I prefer descriptions of experiments and observations.

>With respect to radiation from the ends of a radiator. This can only happen when the radiator is a fraction of a wavelength when the law of equilibrium is violated. The accellaration of charge at the end is without spin applied and tho there is radiation it becomes non directional and unable to overcome the gravitational force and falls within a short distance.

Try the acoustic analogy. Here the all is easy. Quite opposite as in the Maxwell model: "He wants to
present the predictions of his theory on the subjects of reflection and refraction, but the requirements of his mechanical model keep him from finding the correct boundary conditions, so he never does this calculation".

The only reason for Maxwell model is the light polarisation. In his era the polarisation was explained with transverse waves. Now we know (from Clark) that the apparatus is polarised not waves.

I'm sure that W4RNL did a comparison. It might be in here.
<http://www.scribd.com/doc/8511817/Some-JPoles-That-I-Have-Known-4>
<http://www.cebik.com/>
If it's not in there somewhere, a Google will be necessary.

Essentially, the answer was 'not a lot', except that the Slim Jim
version (the one with the folded-over top) had a slightly wider
bandwidth / flatter SWR plot.

No, the meter is measuring the exact same thing in all cases. it always
(indirectly) measures the SWR within itself, which is directly related
to the impedance connected to the output end of the meter. It never
measures the SWR on any transmission line outside itself. The three
cases only explain reasons the impedance connected to the output of the
meter -- hence the meter reading -- changes as the transmission line
length is changed.

Again, the typical SWR meters we use do *not* measure the SWR on any transmission line, except (indirectly) the SWR on the short line within the instrument -- if it even contains such a line, which some don't. I don't know of any way to directly measure the SWR on an intact coaxial line, only on a slotted line.

The SWR on a coax line can readily be calculated, however, from measurements it is possible to make.

Hello Tony,

If you think cable impedance deviation from 50 Ohms is the problem in
your situation, why not making a resistor bridge type of VSWR meter
(wheatstone bridge)?

By changing the resistor that goes from the source to the output
connector, you can change the reference impedance of the resistor
bridge. For HF and VHF, accuracy is very good when using surface
mount components.

One example is given here:
www.w1ghz.org/QEX/A_UHF+_VSWR_Bridge.pdf

Best regards,

Wim

The radial currents on the capacitor plates are 180
degrees out of phase. A lot of the radiation from the
plates simply cancels.

Ramo and Whinnery say that radiation is "primarily
TEM", i.e. TEM is the "principle mode".

It may be that you are using a lumped-circuit model
when you should be using a distributed network model.
According to Drs. Corum, the lumped-circuit model
starts to fall apart at 15 degrees, i.e. 0/04WL.

The Voltage indication is non directive while the current is directive.
Voltage varies because of impedance and the reactivity causes phase
differences resulting in complex voltages. You should see variations in
both forward and reflected indications.

Functionally, the Bird is best used to minimize whatever reverse indication
without worrying over the accuracy of the derived measurement.

Source record: 15080

I have a 50 ohm swr meter (Heathkit, Drake W4 and Bird) and I am using 70 ohm coax for a dipole antenna on 3.7 MHz.
If I trim the antenna for the lowest reflected power showing on the meters, will the antenna be cut to resonate (or near resonate) frequency or is it possiable the antenna will end up around 100 feet or 150 feet instead of near a calculated frequency length of around 125 to 130 feet.

Guess the real question is can I use a 50 ohm meter with 70 ohm coax and when the reflected power is the lowest, is the antenna system adjusted correctly ?

I don't really worry about it, just stick up some wire and operate. Adjust things so the rig will see a low enough swr the internal tuner will take care of it.

Electrical dipole radiation is known from Gauss time.
For us the two plates (or balls - Hertz used them also) are the two sources
of electric longitudinal waves.
For this reason in 1933 the frequency doubling was observed.
>
> Ramo and Whinnery say that radiation is "primarily
> TEM", i.e. TEM is the "principle mode".

It is easy to say. Tell me if you have ever seen the emitting antenna which
has the "current zone" exposed and the ends covered?
According to Maxwell the tranversal waves MUST be created by AC current. DC
current create the magnetic whirl. AC current create oscillating whirl. Such
oscillating whirl starts the transverse wave. But this Maxwell proposition
is not verified to now.

>
> http://www.ttr.com/corum/index.htm

There are details. For me interesting are only fundamentals.
It starts from:
"Maxwell wrote:
The conception of the propagation of transverse magnetic disturbances to the exclusion of normal ones is distinctly set forth by Professor Faraday in his "Thoughts on Ray Vibrations." The electromagnetic theory of light, as proposed by him, is the same in substance as that which I have begun to develop in this paper, except that in 1846 there were no data to calculate the velocity of propagation." From:
http://en.wikipedia.org/wiki/Line_of_force

The TRANSVERSAL magnetic disturbances have beautifull math. The most beauty math element is the displacement current.

But the magnetic disturbances are creates by AC CURRENT (not voltage).

So if the radio waves are emitted from the current zone of antenna Maxwell is right. If from ends - not.

Maxwell admired Ampere. But each genius works out his own theories. We can choose between them.

This is true to a point. Local codes no problem, BUT in HOA territory
these rules do not necessarily apply. In most cases the HOAs have
modified their rules. The small direct satellite lobby started the
trend. Allowing these dishes they really had to include other TV antennas.

I suggest you contact the manufacturer (http://www.hexbeam.com), if you haven't already. They might have some information they'd share.

When your SWR meter reads 1:1, it means only that the impedance it sees is 50 + j0 (50 ohms purely resistive). If you're using 70 ohm line, the impedance at the antenna could be any of an infinite number of different impedances, depending on the length of the coax. It might or might not be resonant, but that won't make any difference to its performance. Your transmitter will be happy with the load, so the antenna will get the full rated output power less coax loss. It would be appropriate to call that the "correct" adjustment of the antenna.

If the tuner has to adjust for some other load impedance (indicated by a higher reading on the SWR meter), the tuner loss will be added. However, it's likely to be negligible if the SWR meter is reading 2 or 3:1 or lower.

>choose between them.

So, the obvious thing for you to do (as the proponent of an
alternative, nontraditional theory) is to devise an experiment which
can distinguish between these two cases.

Remember, that when a responsible scientist proposes a theory, that
scientist tries as hard as possible to come up with ways to *dis*prove
the theory - that is, experiments which predict a testable result,
which differs from the predictions of other theories.

If the new theory can survive such testing, then it's got some meat on
its bones... and choosing it would make sense.

If it fails to survive the testing, it's wrong... and choosing it
would be mistaken.

If the scientist can't use the theory to make testable predictions,
it's useless... and choosing it would be futile.

If all of the predictions of the new theory are indistinguishable from
the predictions of prevailing theory, then perhaps it isn't really
new.. It may just be a restatement of the prevailing theory in
different words... and if so, choosing it would be entirely a matter
of taste or preference.

If the scientist won't even *try* to use the theory to make testable
predictions which might prove the theory wrong, then s/he isn't a
scientist.

So... how would *you* construct and measure an antenna (and perhaps
modify it and then measure again), in order to demonstrate that your
theory predicts the actual behavior of the antenna better than the
standard theory?

Here's a suggestion: start out with a model of a straight half-wave dipole. Predict its radiation pattern and feedpoint impedance, based on Maxwell's current-based theory and on your own voltage-at-the-end theory. Measure the pattern and impedance.

Now, "bend" the antenna into different shapes. For example - leave the center portion of the dipole in a straight line. Bend the ends in various directions, shaping the antenna into a U, or into a Z, or a C (with the tips close together but not touching). Shorten the center section and split the ends, forming an H (e.g. short radiator with capacity loads on each end).

In each case, predict the pattern and feedpoint impedance based on Maxwell's theory and on your own.

Can you find cases in which the predictions vary? If so, which matches the actual (measured) behavior of the antenna better?

Mathematical beauty is great... but if it doesn't predict the actual behavior of real-world phenomena, it's just beautiful math.

Have you considered a tripod of some sort?

The MFJ-1901 sounds like it might work for you. There's no picture on
their Web site, but there's a PDF of the catalog page at

http://www.mfjenterprises.com/catalog/Pages_51_through_75.pdf

It's on page 61.

It's a 2' square piece of stainless with spikes at each corner to stick
in the ground and some sort of mounting arrangement in the center for
masts. Unfortunately, they want $110 for it.

Ralph,

Your 50 ohm VSWR meter indicates the VSWR that you would expect on a low loss 50 ohm cable adjacent to the meter.

For indicated VSWR>1, there is an infinite set of impedance values that would satisfy the indicated VSWR, and a further infinite set of VSWR values that those impedances would imply on the adjacent 70 ohm line.

If the indicated VSWR was exactly 1, then the impedance at that point is 50+j0 and the VSWR on the 70 ohm line is 1.4.

Now there is a possibility!

My 40m dipole is fed with RG6 coax (75 ohm), and a bunch of ferrite sleeves in the style of a W2DU balun at the feed point. I have used a 75 ohm VSWR meter in that line to adjust (shorten) the dipole length until VSWR=1.5. Now, the impedance at any point along the line varies with displacement, but at some points, the impedance will be R=75/1.5, X=0, Z= 50+j0. Having approximately calculated a convenient length, I have cut the line 2m longer, inserted a 50 ohm VSWR meter at the tx end and trimmed (shortened) the coax until the VSWR(50)=1:1. There it is, a shortened half wave dipole, fed with inexpensive coax, very low line loss, and an excellent 50 ohm load for a modern transceiver. This is of course a single band solution, but it is an optimal single band solution.

The example above indicates that you could see a perfect VSWR on your 50 ohm meter. You are unlikely to find the solution by chance alone, but

taking a systematic approach, you can find the solution.

Owen

You SHOULD know better, Elmo. There are some restrictions an HOA can
place on a homeowner, but they are few. Here is a link to the FCC site:
http://www.fcc.gov/mb/facts/otard.html

the FCC premption (aka OTARD rules) is the key thing here.. The HOA
can't really do anything if it fits in the FCC guidelines.. dishes <1
meter, OTA TV any size.

Surveyor's tripod... Much more rugged, adjustable. A CST brand one might set you back $130 at Home Depot, but that's not the cheapest source.

Crain brand aluminum tripods show up online at $60-70 on sale.
(e.g.
http://www.engineersupply.com/crain-aluminum-heavy-duty-tripod-flat-head-22210.aspx
from googling.. I've never used this vendor..)

You want something cheaper... what about a standard steel fence post (T-stake).. hammer it in, hook the antenna up, and you're done. Use a car jack to pull it out when you're ready to go.

Or, one of those bases for a patio umbrella. Either the cast iron or concrete ones, or the ones you fill with water or sand.

Or, some antiskid base (a little spike, like a tent stake) and some nylon rope guys to tent stakes, or weights.

I want to put up a Spi-ro short 160 as a W9LT/K8UR vertical dipole. The coils have a brass screw at each end. How do you securely attach the wire to each end so that it will last through wind storms and the like.

I had one up as a dipole L I used good connectors but the wire just pulled loose.

I am looking for ideas!

What I used was a steel fence post driven into the
ground by a fence post driver device. When I finished
with it, I wrapped a cable around the base, hooked
it to my trailer hitch, and pulled it out of the
ground with my GMC pickup.

I know, but its fun asking the one pertinent question that he can't answer.
he keeps saying i reject his addition of the (t) term to Gauss' Law, and
won't accept the answer that it is redundant since the law is not dependent
on time, it is true for all time. So the (t) is not necessary at best and
misleading at worst... you can put it there, but it doesn't mean anything...
its kind of like saying f(t)=f(t), a simple truism.

Nice thing about the Winegard SquareShooter is it resembles a dish
though my neighbors might think I don't have a clue how to aim it.
It's opposite where all the little dishes are aimed. They would have
laughed if they had seen the spectrum analyzer on the driveway next to
the car. I was on the roof with binoculars to see the screen.

When I lived in Miami; there was a subdivision in Miami Lakes that had
banned TV antennas (before the FCC ruling). A homeowner had constructed
some form of "artwork" with a TV antenna in front of his house. It was
positioned toward the sky, unusable, but unmistakably a TV antenna!

101. Question about EZNEC simulation of a radiating coax line

Newsgroup: rec.radio.amateur.antenna
Date: 2009-06-03 04:11:52 UTC
From: ve2pid <ve2pid@videotron.ca>
Message-ID: <e9ab61ab-7da1-4412-bfd2-4a396f105abf@h2g2000yqg.googlegroups.com>
Source record: 15013

We can use EZNEC to simulate the radiation of a coax with a wire as suggested in the help file "The radiation properties of a coaxial feedline can be modeled by connecting a wire of the coax shield's diameter to the point on the antenna where the shield connects."

We then see that the current has a maximum somewhere along that wire.

My question: Why do we have a maximum? Is is because some current is also going up from the source outside the coax?, In that case, some kind of constructive and destructive interference could happen on the outside of the coax due to phases differences between the two currents, creating maximum and also nodes.

Or is there another reason explaining that maximum?

102. Re: Question about EZNEC simulation of a radiating coax line

>
> Or is there another reason explaining that maximum?

The current can be caused by either of two mechanisms, or both:
conduction or induction.

Conducted current occurs when, for example, a coaxial line is connected to a dipole. Current from the inside of the shield splits and part goes into the antenna and part goes down along the outside of the shield. This can be effectively stopped with a current balun (common mode choke).

Induced current will be zero if the transmission line is symmetrically placed with respect to a symmetrical antenna which has equal currents in the two halves. But in other cases, the fields from various parts of the antenna won't sum to zero at the location of the transmission line, so current will be induced on it. Current baluns can reduce this current also, but it generally takes at least two, spaced a quarter wavelength apart.

Now for the question. You have a maximum for the same reason you have maxima and minima along an antenna -- in fact, a transmission line with common mode current *is* an antenna, and radiates the same as any other one. The maxima and minima can be explained as the envelope of traveling current waves reflecting from an open end (or current balun or other discontinuity) and interfering with each other. These are known as standing waves, because the positions of the maxima and minima stay in the same places and don't move. A lookup of "standing waves" will bring you a lot more information, and I'm sure some good graphics, to further explain it.

Absolutely! My first duty station was an intercept site in the Philippines,
then Hanza, then sea duty on an admiral's staff (Second Fleet Commander).
There wasn't much I hadn't seen by the time I was 25. I made CPO the next
year and was dubbed "The Teenage Chief" for my youthful appearance.

I'm 66 now and smiling slightly, content at how well things have worked out,
thanks to that lucky beginning.

Clifford,

Turn radius is about 12.5" for a 2m broadband hex.

It should be possible to get very deep and narrow F/B nulls by
adjusting the Driver/Reflector end spacing at some cost to the VSWR.

But here are the two possibilities.
1. The dipole radiates the transverse wave from centre,
2. The dipole radiate the two COUPLED longitudinal waves from the two ends.

In the both cases the antennas (emitting and receiving) must be parallel.
Which place radiate the radio waves?

The traditional theory is the acoustic theory. The nontraditional theory is
the Maxwell model. In his model the transverse waves propagate in a solid
body. Maxwell devised many experiments. One of them was the famous MM
experiment. But Maxwell dead before the result.

I am sure that somebody young do it. Maxwell would be happy.
>
> Mathematical beauty is great... but if it doesn't predict the actual

Math is still necessary in schools. But in this case the math will be saved.
The Maxwell equations were the same like the Helmholtz for the fluid
mechanics. Now the same math is taught in the two subjects (fluids and EM).
Very often the same teacher do it.

Roy, since you understand the above, you must also
understand that the mostly unchanging phase of that
standing wave current (relative to the source current)
cannot be used to predict the delay through a wire or
a loading coil.

How about correcting your previous postings on that
subject? Your reports of unmeasurable phase shift
through loading coils are supported by EZNEC and
are completely meaningless as far as predicting
the delay through a loading coil or even through
a wire.

http://bfn.org/~bn589/antenna.html

Plug in the frequency and hit calculate for a 3 element Yagi.

You can make it out of a piece of wood and some stiff wire. Feed it with either
300 ohm twinlead or coax.

If you radio has a 300 ohm connection (two screws) use twinlead, if it has
a single round hole, use coax cable.

you might start with something simpler:

start with a dipole, two 1/4 wave wires one connected to the center of the
coax and the other to the shield (the outside copper braid), or if you
use twinlead, one to each side.

Play with the the location and position (up and down or right and left)
and the angle of the antenna. If you drew an arrow pointing to the station,
it should cross the dipole where the wires connect if it is horizontal.

If that almost works, go to a 1/4 wave vertical (one wire sticking
up with a 4 wires of the same length hanging down. Connect the vertical to
the center wire of the coax or one of the twinlead wires and the four downward
ones to the shield (other wire). The downward ones should be arranged in a
circle around the vertical, e.g.:

downward downward

vertical (up)

downward downward

If that does not work, build a 3 element beam.

If that does not work, see if they have an Internet feed. :-)

Geoff.

What do you have for an antenna now and what is your "normal radio".

A piece of junk boombox. Emerson Model PD6607. The antenna is the
antenna sticking out the top of it.

Just about any antenna will be better than that if you mount up in the
air.

The trick will be connecting it to the radio if there isn't an existing
connector for an external antenna.

Hi "Sal"

I share your thoughts about a pattern range. I recently talked my buddy into writing a program that plots Elevation Plane patterns of an antenna when scaled to a frequency sent from any Polar Orbiting Satellite. I use it alot using the 137 MHz beacons sent from NOAA satellites. Some HAM satellites could be used. There are also L-band beacons sent from the NOAA satellites.

I am trying to validate impedance values I am measuring with my MFJ-259B. I want to do this by using my MFJ-993B auto tuner. The tuner uses a simple L network to create the conjugate match. I want to take the final inductance, capacitance and swr values from the auto tuner digital display after matching is completed and back calculate the impedance that the tuner is seeing. Is there an online calculator that will do this?

Many thanks for replys.

Wouldn't it be easier and much more accurate to make a known load out of components close to what the MFJ-259B reads?

It also will be a frequency indepedant "calibration" if you keep the component leads short.

Jim,

I am concerned about an RF field from a local broadcast that may be causing issues with using the low power MFJ 259B. When I use the auto tuner I am tuning at 10 watts so plenty to counteract any local rf on the antenna. I really need to back calculate an impedance from the inductor, capacitor, and final swr from the auto tuner.

Ignorance makes a lot of things seem incredible.
Not at all incredible according to the Fig. 1
graph that you referenced a few days ago at:

http://www.ttr.com/TELSIKS2001-MASTER-1.pdf

Here's how to do it. Draw a horizontal line at
0.04. Where it intersects the lines on the graph
are the real-world coils exhibiting a VF of 0.04.
If you need help drawing that line, send me an
email.

Hint: Those large loading coils are slow-wave
devices described in my Ramo and Whinnery
college textbook from the 1950's. It's on page
410 of the 2nd edition of "Fields and Waves
in Modern Radio", (c)1944, 1953 (the year you
were born). Isn't it about time you read it?

The approximation they use for vp (phase velocity)
is c*sin(pitch-angle)

> I thought you were going to send me the coil
> so I could measure it.

The coil has been chopped up and used in numerous
projects including my Bugstick article. Don't you
or your students know how to wind a coil? Do you
need step by step winding instructions?

Likely the simplest thing to do is open it up and find the connection
to the existing antenna, then add a connector wired to the same place.

FS: Yaesu G-400RC(like G-450A except no special plugs required for cable hookup). The rotator and controller work well and are in very good shape cosmetically. Cable hooks directly to rotor and controller/no plugs required. This rotor and controller have not been used much. I can send pictures upon request. Price is $140 plus shipping. Thanks, Charlie Hugg, K5MBX

How can you connect a better antenna to a radio like this? I don't
mind taking it apart a bit.

Hi Greg

If you are willing to construct the Yagii, it would be possible you can couple it to your BoomBox by looping the "twisted pair" from the yagii around the case of the radio. Maybe you could experiment with twisting the twisted pair around the antenna you now pull out for the VHF range. It is possible that you will see some improvement by making a circular loop with the wires in the twisted pair and position the loop near the present (pull out) antenna.

OK, that's a different problem.

Have you concidered this if it is a general problem for you:

A little knowledge and logic will make it clear.
My 75m Texas Bugcatcher coil is self resonant
at 8.2 MHz which by definition makes it 90 degrees
long. 90 degrees at 8.2 MHz in free space is 30 feet.

The coil is actually 6.5 inches long, i.e. 0.542 feet.

0.542/30 = 0.018 which is the VF of the Texas
Bugcatcher coil at its self-resonant frequency.

The Texas Bugcatcher coil is 4 tpi. The coil with
the VF = 0.04 is 10 tpi. It all makes sense.

Why didn't you say that the first time?

Tom Rauch (one of the designers of the '259B) posted this info re interference:

"BC interference causes the bridge in the analyzer to remian (sic) unbalanced even with very low SWR, so the analyzer will read a fixed minimum SWR when BC interference. It will read that way on any frequency from dc to daylight. For example if the unit falls asleep the SWR meter won't drop to zero. That's an indicator of BC interference or external voltages being applied to the measurement port."

Guess I was in a hurry and just wanted to know if I could back
calculate the impedance (R +- jX) my auto tuner is seeing based on the
inductor, capacitor and final swr values it displays after a "match is
achieved. I would still like to do this. Dave gave me a link and of
course I can do it manually with a Smith Chart (I think lol).

Thanks. Now there's a bit of info I didn't have. So if the 259B is
behaving normally, when it enters "battery save" mode the swr value
should drop to zero. If not, there are external voltages on the
antenna port. I think I will check this out with a 100 ohm resistor
across the antenna port. 2.0 should drop to 1.0 or zero when "battery
save" kicks in.

By the way, the broadcast station is FM at 105.5 MC.

If you are right then I would no longer be ignorant, and you would still be boorish and asinine.

You seem reluctant to have your coil tested. I promise to return it to you immediately after I make the measurements.

If I make the coil and the results turn out not to support your contention, you would contend that the coil was made incorrectly. It's better that you supply the coil - along with your claims about it. I'm ready to be amazed, Cecil.

Nope, I won't do that. Any large air-core loading coil will
do. All it has to satisfy is the Corum test on page 4:

5ND^2/WL < 1

I'll send you an EXCEL file that makes that test.

Many thanks Owen. I just confirmed I have a BC interference issue.
When I placed a 100 ohm resistor across the 259B antenna terminal, the
unit correctly read 2.0 (well actually 1.9) swr, 100 ohms R and 0 X.
When it entered "battery save" the analog swr and impedance meters
both dropped to zero. The digital display stayed the same.

When I hooked my antenna up the analog swr meter only fell to 1.4 when
the unit entered "battery save" mode. The impedance meter did drop to
zero. When I installed a 4:1 balun at the antenna feedpoint the swr
fell to 1.2, but still not zero when the analyzer entered sleep mode.
Apparently the BC signal is at least to some degree differential in
nature on my feedline.

Anticipating all this, I wrote MFJ about the usefullness of their
their tunable analyzer filter to combat a strong FM broadcast signal.
They replyed that it would work. I wonder how well. The tunable filter
costs around $100.00.

Use the TV antenna.
It won't matter too much if you use twinlead or coax. You can just put a "
F" connector or screw terminals into the radio as above. I prefer to use a
300 ohm balun from the 75 ohm coax for isolation though because of the
possibility of AC leakage to the TV chassis.

If I'm reading you right, the gap between the ends is the
salient factor here. Suggestions on how big a gap to try
first? Something like 3cm?

Sorry for the newbie-ness. Been doing electronics for 30
years, but only now getting into radio and have never tuned
an antenna. Sorta understand EM fields, but don't have any
RF test gear yet, except for my very nice VK3YNG sniffer
(google it). Maybe I should borrow/buy one of the little
fox-or transmitters to tune up an antenna, but it'll be too
late for this weekend's national foxhunt champs in Mt Gambier.

Exactly in 1638:

"1638 - Rene Descartes theorizes that light is a pressure wave through the
second of his three types of matter of which the universe is made. He
invents properties of this fluid that make it possible to calculate the
reflection and refraction of light. The ``modern'' notion of the aether is
born. " From: http://maxwell.byu.edu/~spencerr/phys442/node4.html

The next:

"1717 - Newton shows that the ``two-ness'' of double refraction clearly rules out light being aether waves. (All aether wave theories were sound-like, so Newton was right; longitudinal waves can't be polarized.) "

In the History you find how many people analysed the issue: longitudinal vs. transversal. In 1905 all stop.
But after 1905 peole build antennas. And they do not worry what the radiation is like.
Sunner or later the issue appears again.

Clifford,

There are two styles of hexbeam: the older design which has a W-shape Driver and a W-shape Reflector, and which I call the "classic" on my web site; and my newer broadband design which has a W-shape Driver and a U-shape Reflector.

I found in my lab notebook a 2m version of the broadband style; its dimensions are: half-Driver 21"; Reflector 40"; end gap 2.5". I think I assumed wire construction using #14 bare copper. That would give a hexagon radius of 12.5".

When I model this with EZNEC I see about 3.8dBd Forward Gain and 19dB F/B with VSWR=1.4. The problem is that the rearward response is very smooth and "well behaved" so probably not much use for DF.

If I increase the end gap to 5" the Forward Gain and F/B remain about the same, but the azimuth pattern devlops deep side nulls (38dB) at plus and minus 130 degrees which may be useful. The VSWR deteriorates to 1.8:1.

Hopefully that may give you a starting point for experimentation. If I get a chance I'll try some modelling experiments on the classic design also.

73,
Steve G3TXQ

Steve, thanks. Hopefully I'll discuss it over the weekend
with some of our foxhunt folk and perhaps try some experiments
after that. But you're right, the lobe pattern might be simply
inferior.

Yes, that article described the process by which I arrived at the
broadband version.

Since then there have been a couple of write-ups in the monthly
Antenna column of RadioCommunication magazine, and RSGB published the
design in their recent book "Building successful HF antennas". You may
also have seen Leo's (K4KIO) constructional article in the March
edition of QST. All that has generated quite a lot of interest in the
antenna.

I try to avoid exagerated claims for the design - at the end of the
day it's a "compressed" Yagi and performs as such. But it does provide
useful directivity over the five bands 20m thru 10m, with a single
feedline, in a size which suits those of us that don't have a lot of
space. It's also pretty easy to construct from readily-available
materials, although a number of folk now supply complete kits,
including K4KIO and more recently DX Engineering.

Thanks for the reply, Steve. As for exaggerated claims, I'd have to give the award to the designers of (and explainers of the "theory" behind) the Crossed-Field Antenna (CFA). (Of course the CFA has been the subject of numerous antenneX articles but I'm not placing yours in that group!) 73s,

Friends,

I recently purchased a Sangean DT-400W to replace my trusty DT200VX.
Unfortunately, my new one has an annoying grinding sound that plays in
the background of whatever I'm listening to. This is particularly
frustrating when I'm listening to quiet classical music on the local
FM station. Any idea what this could be, and how I can fix it with
home tools?

Thanks,
TG

you can do it with an Excel Spreadsheet..

You know that at "match" the impedance looking into the tuner from the antenna is the conjugate of the impedance looking into the antenna from the tuner.

If you assume your transmitter is 50+j0 ohms (not a good assumption.. but you could make it closer to being so by putting a 10dB pad between Tx and tuner, for instance)

Then, you calculate what the impedance the tuner is using the L and C values (I assume it's a series L and a shunt C) ... you'll either have:

TxR plus L, shunted by C
or TxRshunted by C, then series L

A spreadsheet like XLZIZL does it in a flash.

Hi "Sal"
If you ever get involved with that Pattern Range, Patrik Tast publishes information on his program on the web. Everything Patrik does is *hobby related* and available free. Nothing I do is sophisticated or difficult to reproduce or to improve upon.
I was using Excel to plot the RSSI level before I asked Patrik to make a program to display the signal strength in polar form. I can get actual patterns that Very closely resemble EZNEC plots.

Thanks Ian. That is the type of calculator I am looking for. However,
this one requires both source and load impedance as input. I am
looking for one that will allow you to specify the source impedance
(50+j0), fill in the capacitor and inductor values, and then tell you
what the matched load side impedance is.

That is a trivial problem. What configuration?
What does the schematic look like?

(50+j0), fill in the capacitor and inductor values, and then tell you
what the matched load side impedance is.

Hi dykesc

I may be missing something. But, if the objective it to learn if the
local 105 MHz signal is actually introducing error into your impedance
measurement, only a few Smith Chart Polts are needed. You know the path (on
the Chart) the shunt reactance will have taken while being adjusted to make
a "match". You also know the path the series reactance took. Start from
the Chart center and move the impedance along the circles of constant
resistance for the series reactor. Move along the circles of constant
admittance for the shunt reactance. When the Xc and Xl are both known, and
you know which is closest to the "transmitter", it seems that a "program" is
unnecessary. What am I mising?

Hi "disc"

I can model a Quadrafilar helix antenna with EZNEC. Roy has made it easy
to model helix antennas.
I can also offer you an antenna design concept that performs better than a
Quad Helix for an antenna located on Earth and expected to have a
hemispheric coverage with Circular Polarization. Google DCA APT antenna
for satellite reception.

Fine, for doing a couple or three. Now do it for a dozen measurements
at different frequencies, especially if you have to convert L and C into
Z for each measurement. A program or spreadsheet is nice to have,
because it automates the tedious calculation.

Heck, if you have a RS-232 interface to the antenna tuner, you can
automate the whole process. Quod fecit.

By the way, the assumption that the run of the mill ham rig has a 50 ohm resistive output impedance is not necessarily valid. In practice, nobody cares.. they just adjust until the reflected power is minimized. But if you're trying to use the tuner as a measuring instrument (essentially, the variable part of an impedance bridge), it's important.

By the way, this comment above is another assumption in that it lacks
a quantifiable. I find it offered quite often as a negative assertion
to which the several many posters who offer them never provide an
actual value to prove what the run of the mill ham rig is, much less
is "not." Rarer, indeed, is any effort put forward by those posters
to show they have attempted to quantify their own equipment.

As there are posters here who have performed this work, shown their
data, and such data follows conventional design considerations (which
is easily revealed within the page cited at http://www.wy2u.com/);
then these assumptions dressed in denial are rather unprofound proofs.
As this topic has been visited many times, and as it quickly descends
into equally unsupported claims (although often annotated with vague
references and citations that are quickly demolished); I doubt
anything said here is going to sway those assumptions.

As an amusing exercise (I anticipate none will tread down this path),
the page at http://www.wy2u.com/ offers a means to test your own rig's
Source Z - if, in fact, you can cope with translating your tuner's
settings into picofarads and nanohenries, and if you can obtain a
known mismatch. These impediments are Herculean to most,
unfortunately.

Hi Jim

As you can see, this plan to 'double check" antenna impedance by relating the impedance to that which the tuner produces, is very limited in its accuracy. One might say *why bother*. My thought was/is, the original poster asked for an online calculator. When that calculator was given, and he still asked for more, I thought it would be helpful to point out how easy it is to use the Smith Chart to get some insight into evaluating his impedance meter. It is my opinion that extensive calculations with a computer program are not able to provide any exact answer to the question about actual antenna impedance when only the tuner Xl and Xc are known. The Smith Chart is a great tool for estimating how impedance matching can be realized. I assummed that the OP could possibly benefit from knowing how easy it is to estimate antenna impedance using the Smith Chart if it can be assummed that the LC circuit is known and that the resultant impedance is 50 ohms. Shunt reactances move the impedance along the circles of constant 1/R and series reactances along the circles of constant R.

You want to specify the ATU input impedance which is independent of the source, not the source impedance (which you don't know or care about). Hams often confuse the source impedance of a transmitter and its required load impedance.

Do you intend treating the ATU as a simple two or three component network using ideal components (no loss, no stray capacitance)? Will that approach give accuracy either adequate or comparable with the many other techniques used?

I have thought about this in the past, mainly the prospect of a relay switched autotuner that reported a calculated load Z based on the found matching solution, but I concluded that it was not likely to be of reasonable accuracy over the tuner range.

If you want to measure Z using an instrument based on a broadband detector, you need to use sufficient power that the broadband detector is dominated by the test signal. There is at least one instrument for the ham market that purports to make such measurements at normal transmitter power. IIRC, R&S used make a commercial product, but it wouldn't have come cheap.

There is at least one other low level antenna analyser that represents that it is less affected by interference than the '259B.

If I were looking for an instrument, I would desire one that could refer the measurements to a point closer to the antenna (eg the feedpoint) given the characteristics of the transmission line between the measurement point and the desired reference plane.

VNAs will peform this calculation, but most low cost VNAs use a broadband detector and low power, so they are susceptible to interference when used on antenna systems.

It's hard to tell, but he's probably referring to the curl of a
magnetic field which he obviously doesn't understand. The idea of
a "pressure-like electric wave" is pure fantasy.

In a quick scan of the replies, one thing I didn't see mentioned is that if the indicated SWR is not 1:1, then there's an uncertainty in your answer. For example, a 1.1:1 indicated SWR, taken with a meter calibrated accurately to 50 ohms, could represent 55 ohms or 45.5 ohms, or any other impedance with the same magnitude of reflection coefficient relative to 50 ohms. If you start at 55 ohms, you'll get a different answer for a particular L and C than if you start at 45.5 ohms. Of course, each of those will be different than the answers for other phase angles of the same reflection coefficient. You can get rid of that particular uncertainty by adjusting to 1:1 SWR. Of course, you're still left with other uncertainties, but since you have control over that particular one (presumably), at least get rid of it.

I'd use WinSmith to do the calc you mention, or hack a simple spreadsheet if I had several to do, or put the values into Matlab or Scilab.

Cheers,
Tom

Thanks Jerry. No you aren't missing anything other than the fact that
my familiarity with Smith Chart analysis is limited to working through
a few exercises in the last chapter of the ARRL Antenna book. I will
be looking for more Smith Chart tutorial info on the web and am
certain I can get myself up to speed enough to start working with
conductance, suseptance, admittance, etc.

Thanks again. From your post it appears it will be a straight forward
exercise once I get my head around it.

Probably would be as accurate as any other gear we can afford Owen.
I'm going to suggest that MFJ make that a feature on an auto tuner. I
don't live to far from their headquarters in Starkville, MS. I have a
son going to Mississipi State there and have never been to their
facility. This will make a good topic of conversation.

I looked on the R&S site. The only thing I found was a "Field Fox"
analyzer selling for $7,599.00. It is the cat's meow, but guess I'll
have to stick with my 259B.

> There is at least one other low level antenna analyser that represents

Now that would be a great feature. Input your line type and physical
length and the analyzer does the transform. Lots of programs available
on the web for that, but would be nice to have at your fingertips.

> VNAs will peform this calculation, but most low cost VNAs use a broadband

Yes, I thought about that Tom. The premise of my undertaking is that I
can achieve a 1:1 match. At times I'll bet my tuner won't make it.

Probably would be as accurate as any other gear we can afford Owen.
I'm going to suggest that MFJ make that a feature on an auto tuner. I
don't live to far from their headquarters in Starkville, MS. I have a
son going to Mississipi State there and have never been to their
facility. This will make a good topic of conversation.

Unless they can find someone elses to copy, it won't happen.

> What does the schematic look like?

The auto tuner is a simple LC network (series inductor, shunt capacitor) Cecil. It reports the inductor and capacitor values and the side of the network the shunt capacitor is on (transmitter or antenna). Of course it reports final SWR as well.

For instance, at 28.7Mhz it matched with an inductor value of 0.17 microhenries and 0 pF at an SWR of 1.0 (1:1).

My MFJ-259B reported 25-j11 at 28.7 Mhz which obviously is not in agreement with the auto

Thanks Cecil

Actually, I did a casual search for such data, but couldn't find any
for the "run of the mill" solidstate 100W ham rig . There is a fair
amount of data for one tube rig or another). There is some data in
the Moto Ap notes by Granberg, etc, that's reasonably representative,
but it doesn't include the effect of the inevitable LPF on the output.

So, looking at things with which I have practical experience and
measurements.. MMIC amps tend to be be pretty flat over octave
bandwidths, but I don't think they're representative of ham rigs with
either FET or Bipolar output stages (which have to cover multiple
octaves, in any case). Hot microwave FET amps have output impedances
that are anything but 50 ohms, and designing the output networks keeps
lots of RF engineers employed, especially over temperature and device
parameter variation.

I'd love to see some real data for ham rigs.

 Rarer, indeed, is any effort put forward by those posters
> to show they have attempted to quantify their own equipment.

Perhaps that's because this is, after all, "rec. radio", as in, nobody
is paying people to comment here, and unless you have a particular
need to know the output Z, it's not worth it to spend the time to
measure it. As previously commented, either you're in the "no tuner"
category, and you tolerate whatever mismatch there is on both ends of
the transmission line, or you have a tuner, and you tune for "best
match", with whatever the output Z is.

For all we know, the folks that complain about not getting a good
match on a Brand X antenna, when everyone else does, have a rig with a
bad match on the output.

>

My original contention is that if you're going to measure Antenna Z by
using an autotuner and seeing where it tunes, one of the underlying
assumptions is that the other side of the tuner is 50 ohms.

In reality, having actually done this (e.g. use LDG AT200PC tuners to
measure the mutual impedance matrix of an array), I think the
resolution/step size of the tuner is a bigger problem with the
technique. Given the availability of low cost VNAs for the ham
market, that's a MUCH better solution to measuring antenna impedances.

Looking at that page, I don't see an obvious link.

Measuring the output Z of the transmitter would be an interesting
exercise.. for microwave circuits, one uses a load-pull setup..

The challenge is, of course, that the amplifier is an active device,
so the output Z probably changes depending on the load. It's not like
an antenna, where the feedpoint Z at a given frequency is pretty much
constant, regardless of the incident power.

I doubt it. Again it relates to the loss characterisation of the
components. If you could do that, the device could also calculate its own
efficiency... now that would be a feature that would kill the market!!!

http://w5big.com/ AIM4170.

The operative word in my statement was "represents". As to whether it is
actually better, and whether it is adequate, you will need to depend on
owners. The badging of the instrument as AS doesn't add value for me.

Problem is that many of the people using these things see them as a magic bullet and don't actually understand transmission line fundamentals, which questions their opinion of the performance of the instrument.

>
> That has become very obvious to me.

We haven't dispensed with the need for a good reflectometer in capable hands, or is it just that we haven't dispensed with the need for capable hands?

BTW, for referring measurements at one place to another, TLLC at http://www.vk1od.net/calc/tl/tllc.php may be of interest. It would be a challenge to incorporate those calcs in a small 8 bit microcontroller, their capacity and performance on logs, hyperbolic cosines, etc is the issue. Probably why most of the tools that do this, use a client on a PC to do the calcs and presentation.

Thanks Jerry. No you aren't missing anything other than the fact that
my familiarity with Smith Chart analysis is limited to working through
a few exercises in the last chapter of the ARRL Antenna book. I will
be looking for more Smith Chart tutorial info on the web and am
certain I can get myself up to speed enough to start working with
conductance, suseptance, admittance, etc.

Thanks again. From your post it appears it will be a straight forward
exercise once I get my head around it.

73
Dykes AD5VS

Hi Dykes

As you may already know, the Smith Chart is simply a plot that shows *all*
impedances with a real resistance. Smith displays the impedances so the
user can quickly see how any given impedance can be adjusted by adding any
series or parallel resistances and/or reactances. Series inductance moves
the impedance "upward" along the circles of constant Resistance. Shunt
inductance will move an impedance along the circles of constant conductance.

Hi Jim,

Searching and measuring are worlds apart.

>There is some data in
>the Moto Ap notes by Granberg, etc, that's reasonably representative,
>but it doesn't include the effect of the inevitable LPF on the output.

Now, this is the most curious statement of them all. Every LPF that
is mounted in any Ham grade HF rig is designed with both a 50 Ohm
input Z and a 50 Ohm output Z. This is easily verified through the
same page that does the calculations, or through trivial math for the
individual components' Z.

>So, looking at things with which I have practical experience and
>measurements.. MMIC amps tend to be be pretty flat over octave
>bandwidths, but I don't think they're representative of ham rigs with
>either FET or Bipolar output stages (which have to cover multiple
>octaves, in any case).

Why not? Those same HF rigs have switched LPFs for each octave. This
has been a staple of solid state design for 30+ years. Consult a
schematic.

>Hot microwave FET amps have output impedances
>that are anything but 50 ohms, and designing the output networks keeps
>lots of RF engineers employed, especially over temperature and device
>parameter variation.

And for those same 30+ years of HF solid state rigs, their power transistors have had (and still do) output "native" Z of several Ohms. This is not a remarkable deviation by the progression to FET, the FET is simply a different "native" Z with a different transform to get to the same 50 Ohms. Consult any schematic where the Z transform in the output transformer is clearly in a Z step-up in the proper ratio. This stuff has been slam-dunk for decades.

>I'd love to see some real data for ham rigs.

Mine (Drake TR-7 and Kenwood TS-430s) exhibit values that vary around 50 Ohms with a low of 35 Ohms and a high of 70 Ohms in the margins. Those rigs also suffer in those margins. Measurements were done by pull, by substitution, by looking into the antenna connector with an RF Bridge and all confirmed by simple reverse design principles. Variations between any method rarely departed from one another, and never from the values above. Walt Maxwell has reported his own data (tube set albeit, but the principles of transformation and exhibited Source Z are not dependant upon technology).

>> ï¿½Rarer, indeed, is any effort put forward by those posters

This apology condemns the hobby to the lowest common denominator. If it were meaningful, we would be reading yet another miracle antenna claim without hint of skeptical enquiry braced with theory, hammered with models and test gear behind it.

>As previously commented, either you're in the "no tuner"
>category, and you tolerate whatever mismatch there is on both ends of
>the transmission line, or you have a tuner, and you tune for "best

Every problem is reduced to those two options?

>For all we know, the folks that complain about not getting a good
>match on a Brand X antenna, when everyone else does, have a rig with a
>bad match on the output.

That is arguably so, and my experience described above about operation in the margins would suggest so. But it would be a very atrocious Source Z that would lead one to that observation. My experience was noted only by close examination, not a smoking finals deck. The complainants experience would argue that the rig is flat out broken with the drivers pushing 5 or 10 W through incapacitated finals.

More likely the complaining is related to issues outside of the rig.

>Looking at that page, I don't see an obvious link.

Can you supply a known mismatch? It is inputable at that page;
Can you supply a known C from a tuner that has matched that load? It
is inputable at that page;
Can you supply a known L from a tuner that has matched that load? It
is inputable at that page;
Can you adjust the source Z when the tuner has matched that load? It
is inputable at that page.

This is a substitution method.

These steps reveal the common design criteria for building an LPF for
an output stage. Consult "Filters, Image-Parameter Design" in any
copy of "Reference Data for Radio Engineers." Consult, further,
"Filters, Modern-Network-Theory Design" in the same source. Read the
caption of Fig. 2 in that section:
"The Generator and Load must be considered part of the filter."
In the supporting text:
"The generator and load resistors can be assigned any value
between zero and infinity."

Fig. 25 shows the mathematical impact of Source Z (as R or G) to the Network response. It also shows the Load Z as a mirror R or G in symmetry to the source. These commonplace considerations are repeated in Fig. 27, 28, and 29.

Consult Fig. 34 where both ends can be "interchanged." And repeated out through Fig. 56.

In the section entitled "Low-Impedance Generator and Load" observe:
"A low impedance generator and/or load may be used with
the above filter by ... an effective turns ratio that transforms
the low impedance to the value required..."
>
>Measuring the output Z of the transmitter would be an interesting
>exercise.. for microwave circuits, one uses a load-pull setup..
>
>The challenge is, of course, that the amplifier is an active device,
>so the output Z probably changes depending on the load.

I've heard that platitude far too many times. Of course it is an active device. Of course the output Z changes with load. Do you have anything more to offer than simple qualitative musings? One could as easily dream that output Z varies with room temperature, with humidity, with time of day, with elevation, and if the total of those variations were capped off with a quantitative measurement of an accumulated ï¿½10%, then the whole list of objections would get hooted off the stage. Give me a metric instead of looking under the bed for spooks.

>It's not like
>an antenna, where the feedpoint Z at a given frequency is pretty much
>constant, regardless of the incident power.

It is also not like a resistor, or a capacitor, or an inductor. Nor is it like an audio amp or its speaker. The output Z is not like so many things that to start this list only leads into an infinity of trivial comparisons that wander the landscape.

So, the output Z is not like the load Z. What significance does that bring?

On the other hand, I have worked with high power Transistor circuits that have acted exactly as resistors, inductors, and capacitors and output Z was exactly like an antenna at a given frequency (or rather input Z, as one design was an active 100W load).

There are a range of formats for plotting "*all* impedances with a real resistance", and Philip Smith found some of them in his quest for what is now known as the Smith chart. It is not simply a plot of R and X, but in fact a plot of the complex voltage reflection coefficient and it can have R and X scales overlaid (along with a bunch of TL related radial scales), and because of the behaviour of transmission lines, G and B scales. The R, X, G, B scales are a consequence of the plot of the voltage reflection coefficient, an overlay, and not the fundamental quantity plotted.

The magic that underlies the Smith chart is the Telegrapher's Equation (or a lossless form for most applications).

Owen

Some theories are taught some not. But people after 25 can use what they
want. It seems to me that engineering people do not use the EM theory.

Theories that aren't taught have probably been dropped for a good reason.
usually because they are wrong or don't do anything useful. I don't know
about other engineers but i use EM theory, all my antennas were designed
using it, and i test it regularly with my own equipment... it has never
failed me.

Actually, you could probably do this with a series of lookup table. A tuner mfr has a fairly good idea (or can get a fairly good idea, with some time to do appropriate measurements) of the loss properties of the tuner components. Based on measuring some AT200PCs with a TenTec VNA, there is *some* interaction between the components, so it's not a perfect linear scaling as you step through the values. The tuner knows the frequency, it knows the L and C, and it knows the parasitic Rs, and it knows that it's "matched", so it should be able to calculate currents and voltages, and figure out loss.

Whether you could do it in a tiny PIC... I don't know.

You'd be surprised.. the question is whether someone is motivated enough to try and do it. There's not much commercial market, so it would be a labor of love, and that requires a somewhat bizarre intersection of someone who takes pride in putting complex math (in both senses of complex) into a limited processor AND someone who is familiar with the relevant equations and their use.

In any case, given that folks have done this sort of thing on Z80/8085/6502 class processors... It doesn't have to be fast.. 10 seconds is a LOT of CPU clock cycles.

In the context of discussing on a newsgroup, I'm willing to spend a
few minutes searching. I'm not willing to spend hours measuring.
Others might. I seem to have recalled seeing some data a few years

Uh huh... and all manufacturers use high precision components, and the
impedance at one end of the filter isn't affected by the impedance at
the other end?

My original point is that, barring measurement, you don't KNOW.
(which is sort of your argument too, eh?)

>
> >So, looking at things with which I have practical experience and

>
> Why not?

Because the MMICs are a totally different design model. To start
with, they're also Class A, while most ham rigs run Class AB. They
also tend to be "detuned" for broadbanding, at the expense of
efficiency. (not all MMICs are this way.. I'm talking about the MAR-n
series, for instance)

> >Hot microwave FET amps have output impedances

Would that the active device has a Z that is constant, but it's not.
Sure, the MRF454 data sheet says the output Z is 1+.2j ohms (or
something like that) at 30MHz, but is it still that at 1MHz?

Looking at a more modern power FET for amplifier use, the IXZ210N50L..
There's a whole page of S parameters, and S22 goes from 0.88@-51deg at
2MHz to 0.43@-117.37 at 14.32 MHz to 0.54@-130.17 at 30 MHz... that's
at Ids =200mA.. bump Ids to 500mA, and the magnitudes stay about the
same, but the phases change, by tens of degrees.

Having actually worked on an amplifier design with similar parts, I
can also say that the datasheet is only a "get you in the ballpark for
the design" tool. The "real parts" (especially when packaged on a
board and attached to the heat sink) are substantially different.

No simple transformer is going to make that look like a constant 50
ohms.
>
> >I'd love to see some real data for ham rigs.

> Those rigs also suffer in those margins.

so the VSWR looking back from the tuner into your transmitter is
1.4:1? A return loss of around 15dB... what's that work out to... an
error of about 10-15% in the "measuring impedance with a tuner"
technique... not bad, but not great, either, especially stacked up
with the other uncertainties..

Good enough to give a "cross check" on another measurement? Maybe...
if the tuner technique showed I had a load Z of 100+50j, and the MFJ
gave a result of 90 + 40j.. yeah, I'd say it is consistent.

Measurements were done by
> pull, by substitution, by looking into the antenna connector with an
> RF Bridge and all confirmed by simple reverse design principles.
> Variations between any method rarely departed from one another, and
> never from the values above.

Although you have to admit that a 2:1 impedance variation isn't a
particularly outstanding "constant impedance load"

Not at all.. just because *I* don't want to spend the time measuring it doesn't mean that the information is of no value to the community. I would venture that of all the data that hams, collectively, could measure, this is actually not as useful as some other data.. It just doesn't have that much impact on day to day operation. Very few hams adjust their tuner by calculating L and C based on measured data, or else there wouldn't be a plethora of articles and posts about "tuning", "pruning", "trimming" and the techniques for doing this, and arguments about whether a Brand X meter is better than a Brand Y meter, etc.

Hams, by and large, adjust their tuners by minimizing the reflected power, and don't much care what the actual component values are. (e.g. what ham tuner actually has accurate dial calibrations in pF or uH?)

Professionals, on the other hand, do CARE, and do make the measurements, particularly if they're doing phased arrays, or designing circuits for mass production, or have to document that their system will work over wide ranges of temperatures, aging, and other effects. But, because they're getting *paid* to do it, they're more than happy to do so. It makes the rest of the job easier.

Obviously not, but I'll bet that it covers over 90% of hamdom (and a lower percentage of the folks reading this thread).

Ahh.. I misunderstood.. I thought you were pointing to process for doing the measurement and/or some measured data. The cited page is

just the calculator for part of the problem.

> anything more to offer than simple qualitative musings?

Sure.. check out the Ixys data sheet. Plenty of grist for "Z varies
with load and frequency"
Phase of S22 varies 40-50 degrees with Ids. That's in your 10%
ballpark
> On the other hand, I have worked with high power Transistor circuits
> that have acted exactly as resistors, inductors, and capacitors and
> output Z was exactly like an antenna at a given frequency (or rather
> input Z, as one design was an active 100W load).

Yes.. but were those run-of-the-mill amateur transceivers? (the
original question).. I have no doubt that it is possible to build
amplifiers with constant Z (to any degree of constancy desired.. heck,
a 1000W amp and a 60db pad gives you a 1mW amplifier with very good
output Z, regardless of what the amp does).

But, does a "designed for mass production and cost target" transmitter
fall into that category?
It's not a published spec
ARRL doesn't measure it when they review rigs

So it's left to someone who cares to do so.

You do not use the EM theory. In EM no electrons. You use electrons:
"Electronics is a branch of science and technology that deals with the flow
of electrons through nonmetallic conductors, mainly semiconductors such as
silicon. It is distinct from electrical science and technology, which deal
with the flow of electrons and other charge carriers through metal
conductors such as copper. This distinction started around 1906 with the
invention by Lee De Forest of the triode. Until 1950 this field was called
"radio technology" because its principal application was the design and
theory of radio transmitters, receivers and vacuum tubes."

Electrons never failed us.
```

if you want to talk with MODERN engineers, then you should use MODERN definitions. i don't know who wrote that wikipedia definition but you would find it very hard to work with just non-metalic stuff in the electronics I know. even the smallest integrated circuits use metalic conductors to connect components and for connections to the outside world. All radios (aren't radios electronic) use metallic antennas in one form or another... check some other definitions:

the branch of physics that deals with the emission and effects of electrons and with the use of electronic devices
wordnet.princeton.edu/perl/webwn

electronic - of or relating to electronics; concerned with or using devices that operate on principles governing the behavior of electrons; "electronic devices"
wordnet.princeton.edu/perl/webwn

the branch of technology concerned with the development and application of circuits or systems using electron devices, including magnetic amplifiers, transistors
www.tki.org.nz/r/technology/curriculum/p85_86_e.php

electronic - Pertaining to the energies, distributions, and behaviors of electrons; see mechanical.
e-drexler.com/d/06/00/Nanosystems/glossary/glossary_e.html

do not 'electronic devices' include transformers?? aren't most of them made out of metallic conductors?? what about capacitors, don't most of them have metallic plates? magnetic amplifiers are most definately made of metallic conductors.

EM or ElectroMagnetic theory does indeed include charged particles. Maxwell's equations are definately based on charged particles. just where does the 'i' term come from if not from moving charges? and where does the charge term in art's favorite Gauss' law that is part of Maxwell's equations come from if not from charged particles??

Take a glance in Maxwell's Treatise. There is the incompressible massles
fluid.
Maxwell did the math to Faraday ideas. But with one exception. Faraday
discovered the atomic nature of electricity (at electrolise).
Maxwell ignored it. He prefered fluids and whirls. Todays teachers also
prefere it.

>and where does the charge term in art's favorite Gauss' law that is part of
>Maxwell's equations come from if not from charged particles??

Each genius wrote his own Electrodynamics. They are in some points similar.
But the incompressible fluid is only in Maxwell's.

the final result of the collection of Maxwell's equations does not rely on
an incompressible massless fluid. It says nothing about the nature of
space, only the relationship between the charges and fields... which is all
that is needed to completely describe charged particle and electro-magnetic
field interactions.

> S*

Rather than using the term "whirls" you should use the term
"cavitation" then you have a good analogy since the clustered charged
particles can be seen as non compressible.
When seen like this then you can use the same equations, which is why
initial introduction
uses the liquid analogy. PV =WRT then can come into play. The main
point to remember
that once the liquid departs from the nozzle of flow cavitation does
not exist and thus gravity takes over. This is the basics of my
combination/ loop dipole antenna where the liquid rotates around the
loop until there is a partial balance such that liquid may reach the
end of the dipole ie high voltage low current which is resonance
because of the phase. Basically the loop is acting as a tank circuit
where it is cavitation is acting as the displacement current. This all
goes back to the existence of the four forces being the basics of all
science in the Universe otherwise known as Classical Physics. The
bottom line "S" is that radiation needs spin (cavitation if you will)
to radiate in a straight line projection away from the hose direction
which a liquid does not have when released from a hose. (Cavitation
is a combination of two vectors which creates spin).
This is the basic reason why Reg used to hang on to the transmission

line theme for a radiator where two parallel lines were accompanied by
a capacitive jumper at intervals
which in conjunction with current flow created displacement/cavitation/
skin depth e.t.c to provide spin, swirl, or what ever you want to call
it

>be looking for more Smith Chart tutorial info on the web and am
>certain I can get myself up to speed enough to start working with
>conductance, suseptance, admittance, etc.

I strongly encourage you to work it through from the basic math:

- Impedances and admittances are complex numbers, with both real
(pure-resistive) and imaginary (reactive) components.

- When you put two things in series, add their impedances

- When you put two things in parallel, add their admittances

- Admittance = (1+j0) / impedance, and vice versa.

The math is quite easy to implement in FORTRAN, or any other
programming language which has native complex-number capability. C
doesn't, alas, and you'd have to use a complex-number library or write
your own. I'm sure that there are standard C++ classes and methods
for handling complex numbers.

Although I haven't yet used the capability, it looks to me as if
modern spreadsheet systems (e.g. Excel, OpenOffice Calc) can deal with
complex numbers. You can't use the normal arithmetic operators (at
least, not in OpenOffice Calc) but myst use special complex-number
functions such as IMPRODUCT and IMDIV and IMSUM.

Not too hard to do, though.

I'd suggest starting out with the simplest calculation (e.g. a
inductor or capacitor, in series with a pure resistance). That one's
really easy, you just calculate the impedance of the reactive
component at the frequency of interest, and do a complex addition.

Then, do an inductor or capacitor, shunted in parallel with a pure
resistance... calculate the reactive impedance, invert the impedances
to get admittances, sum them, invert again to get the final impedance.

Once you can do those two basic steps, you can simply repeat them as
necessary to determine the effect of L and T matching networks, tanks,
and so forth.

The Smith chart makes it easy to do this via graphical means - it's faster than using a slide rule or table of logarithms - but it's very instructive to do the math youself (with the aid of a spreadsheet).

With the Smith chart, it's usual to normalize all of the impedances to your reference value (e.g. divide by 50 ohms), do the calculations, and then denormalize (e.g. multiply by 50 ohms).

Doing so isn't necessary if you do the complex-number calculations yourself... you *can* normalize/denormalize if you wish, but you'll get the same results if you work directly with the raw impedances and admittances.

Hi Jim,

I haven't the slightest idea why your objection demanding "high
precision components" is necessary. Do you have anything that is
quantifiable to sustain this concern? Give us a Monte Carlo result of
those quantified precisions and their impact on Z.

>My original point is that, barring measurement, you don't KNOW.
>(which is sort of your argument too, eh?)

Given decades of lock-step design that conforms to accepted practices,
why would anyone have to measure something to KNOW what it is? These
are exceedingly basic considerations that do not demand differential
calculus to get to the first pass approximation. A simple algebraic
approximation is going to be quite good. Measurement will confirm.

You recite Motorola without context, I will fill that gap:
"The network theory for power amplifier design is
well known but is useless unless the designer
has valid input and output impedance data for
the transistor."

Motorola has for years recited at least three different means to
obtain large signal transistor output Z, and has characterized
individual transistors over frequency in charts. I have enumerated
these in the past to no obvious response from other objectors that
Motorola knows what they are doing (even when objectors recited the
exact same references!), but I will proceed once again:
1. Load pull (which satisfies NOT using small signal parameters);
2. Transistor saturation, current, and supply voltage;
3. transition and diffusion capacitances at the collector junction.

This last method responds to your nervous wondering about low
frequency response (UP TO the highest frequency, Z does not undergo
dramatic changes).

I haven't seen a 13.6V, 100W amplifier deck in the last 30 years that varies one iota from any other - and for good reason: this stuff has been cookie-cutter design for decades using transistors with known and optimized characteristics that haven't varied either. Yes, FETs have emerged in those years, and so have high voltage PNPs and NPNs. Their contributions have only shifted the design points, not the topology, nor the matching principles. With absolutely every new component's introduction, there have been more than sufficient discussion of matching principles that describe their output Z.

>> >So, looking at things with which I have practical experience and

>also tend to be "detuned" for broadbanding, at the expense of
>efficiency. (not all MMICs are this way.. I'm talking about the MAR-n
>series, for instance)

That is not a reason, nor is it different to any great degree. The same issues dominate both topologies. Further, efficiency is not always a goal when it contradicts the need for gain; and both may not satisfy match (as there is more than one form of match: conjugate match and Z match). I don't suppose you have anything quantitative here either, do you?

>> And for those same 30+ years of HF solid state rigs, their power
>> transistors have had (and still do) output "native" Z of several Ohms.
>
>Would that the active device has a Z that is constant, but it's not.
>Sure, the MRF454 data sheet says the output Z is 1+.2j ohms (or
>something like that) at 30MHz, but is it still that at 1MHz?

This is another strange objection. You flatly state it is not, but you are wholly uninformed about it specifically. Your nervousness is odd with its faltering expectation for performance at what the industry generally considers to be a very undemanding frequency. Your question's implied suggestion is: "is the Z for 30MHz the same as the Z for 29.9MHz?", which from your limited perspective (you are really reading a rather thin spec sheet) won't answer either. Study something more encompassing; Motorola has vastly more informed resources than your meager recitation. A simple browse of half a dozen transistors from the same production series provides quite specific details.

My Drake TR-7 uses MRF421s and those transistors are rated at 100W PEP (my rig is rated at 140-150W CW) where their output resistance varies from 1.8 Ohm to 1 Ohm over more than 4 octaves. The spec sheets are

more detailed and do not depart from others of that class. As such, I do not expect your MRF454 would either, but your qualitative expectations are hard to account for and no parts engineer would cut a purchase req from them.

>Looking at a more modern power FET for amplifier use, the IXZ210N50L..
>There's a whole page of S parameters, and S22 goes from 0.88@-51deg at

>at Ids =200mA.. bump Ids to 500mA, and the magnitudes stay about the
>same, but the phases change, by tens of degrees.

Again, Motorola specifically rejects small signal parameterization for power applications. This is, perhaps, your problem with characterizing amplifier issues.

>Having actually worked on an amplifier design with similar parts, I
>can also say that the datasheet is only a "get you in the ballpark for
>the design" tool. The "real parts" (especially when packaged on a
>board and attached to the heat sink) are substantially different.

I have selected, inspected, and validated transistors to Mil Spec and found very few wandered from commercial specification. You must inhabit a very different realm where production lots contain product that are "substantially different." Do you have some quantification for "substantially?" Or is this another example of a technician's shrug?

>No simple transformer is going to make that look like a constant 50
>ohms.

Ah, are we now down to parsing this to "exactly 50 Ohms" where in your objections you offer few quantifications? Does 49 Ohms invalidate the premise and score a home run for the opposing team?

>> >I'd love to see some real data for ham rigs.
>>
>> Mine (Drake TR-7 and Kenwood TS-430s) exhibit values that vary around

>with the other uncertainties..

Not great? You have already suggested it was unknowable, and others state it was immaterial. It gives me pause to have given a concrete result to now find what was unknown is now "uncertain" and what was immaterial now counts for little at "not great."

>> Measurements were done by
>> pull, by substitution, by looking into the antenna connector with an

>> Variations between any method rarely departed from one another, and
>> never from the values above. ï¿½
>
>Although you have to admit that a 2:1 impedance variation isn't a
>particularly outstanding "constant impedance load"

This characteristic that is "not particularly outstanding" was formerly deemed impossible to determine and immaterial by others. I would say that the gulf that I bridged goes a good deal further than demurrals such as yours. As for the sudden emergence of the qualification for "outstanding," that can be obtained if you care to indulge in quantifying what "outstanding" means to you. Am I being set up with an impossible goal to satisfy your point? This performance characteristic that I have published has served an active market for generations; and that in its own right responds to issues of "outstanding." The market would respond: "sufficiently so."

As to could it be better? Without a doubt, and again, design would proceed from knowing the transistor source Z, not "by guess and by golly." This again goes to conventional design considerations that were enumerated by H.W. Bode in the late 30s.

>just because *I* don't want to spend the time measuring
>it doesn't mean that the information is of no value to the community.
>I would venture that of all the data that hams, collectively, could
>measure, this is actually not as useful as some other data.. It just
>doesn't have that much impact on day to day operation.

What a tedious reply in the face of correspondence in other topics that struggle to pass as intelligent discussion. I wonder why you put such effort to responding here if this has so little impact, no relative importance, no relation to design, nor application to "using a tuner to determine Line Input Impedance" (a fully informed topic of great impact on day to day operation, isn't it?).

>Very few hams
>adjust their tuner by calculating L and C based on measured data, or
>else there wouldn't be a plethora of articles and posts about
>"tuning", "pruning", "trimming" and the techniques for doing this, and
>arguments about whether a Brand X meter is better than a Brand Y
>meter, etc.

Your comments to the original poster, then, could have been reduced to one response of one line telling him to abandon his quest by this same logic.

>Hams, by and large, adjust their tuners by minimizing the reflected
>power, and don't much care what the actual component values are. (e.g.
>what ham tuner actually has accurate dial calibrations in pF or uH?)

Do I need to quote that correspondent's post? And if I did, what objection would fall from that? another step descending into

intellectual entropy.

>Professionals, on the other hand, do CARE,

and Hams do NOT. By this standard, our group would dissolve to the merits of photons bouncing waves off each other.

>> Every problem is reduced to those two options?
>
>Obviously not, but I'll bet that it covers over 90% of hamdom (and a
>lower percentage of the folks reading this thread).

90% of hamdom - leaving some several many thousands who are interested is sufficient enough. Not for you? Not enough readers here? Diminishing the level of discourse is not going to build audience to that several many thousand potential, will it?

>> On the other hand, I have worked with high power Transistor circuits
>> that have acted exactly as resistors, inductors, and capacitors and
>> output Z was exactly like an antenna at a given frequency (or rather
>> input Z, as one design was an active 100W load).
>
>
>Yes.. but were those run-of-the-mill amateur transceivers? (the
>original question)..

Yes.. but indeed - how tedious. I have responded to the specific question; I have responded to the specific component; I am responding to correlating designs. Every response is rooted in published and quantified characteristics.

>I have no doubt that it is possible to build
>amplifiers with constant Z (to any degree of constancy desired.. heck,
>a 1000W amp and a 60db pad gives you a 1mW amplifier with very good
>output Z, regardless of what the amp does).

Why does your imposed solution have to come with a crippling hit to efficiency or match? The only inhibition against designing an amplifier to meet your unquantified expectations is the cost involved, not loss of efficiency, not loss of match. You said you have experience in amplifier design, this cannot be such an impossibility can it?

>But, does a "designed for mass production and cost target" transmitter
>fall into that category?
>It's not a published spec

You mean you haven't read the spec. I have seen this objection too. When I've offered just such specs, objectors have then recursed back into how output Z is unknowable and immaterial as if the topic had never been encountered before.

>ARRL doesn't measure it when they review rigs

Now THERE's an authority! Do they measure efficiency?

Hi "disc"

I can help you a little with learning to use EZNEC to model a Quad Helix.
I have a few Quad Helix antennas modeled for 137 MHz. That data is
available to you.
I can show you how to design your own hemispheric coverage antenna that
will perform better than a Quad Helix for reception of signals from polar
orbiting satallites.

What do you want to do?

> those quantified precisions and their impact on Z.

I'm not going to bother. If you care, you can do so, or point to a published summary, rather than spending hundreds of words reciting how to do something we both know how to do.

Again.. without published data from the transceiver maker (whether derived by measurement or analysis, it matters not) or data from somewhere else, I made the initial assertion that since using the tuner to measure impedance depended on the source being 50 ohms (or at least, known Z), one should not blindly assume that a rig has a output Z of 50 ohms. You provided one set of data for your rig (35 to 70 ohms), which does actually bound the problem, assuming that yours is representative of the general class. It might be, it might not. There's no "trivial" (as in spending no more than 5 minutes) way to know.

For myself, I don't care, today, what my rig's output Z is, because everything I use it with doesn't care much (e.g. the auto matching network finds a match, and whether it's matching 50, 30, or 70 ohms, there's not much difference). If I were doing something different (measuring Z with a tuner) I would care, and I'd measure it.

> Given decades of lock-step design that conforms to accepted practices,
> why would anyone have to measure something to KNOW what it is?

Funny thing, then... there's remarkably little published (as in findable with google) data on the output impedance of solid state transmitters. Yes, the designs are pretty cookbook, but there's a dearth of published test or analysis (I maintain, of course, it's because nobody really cares much in actual application situations).

For other RF power amp applications (like plasma etchers, RF heating, etc) there IS data, but those devices aren't ham transmitters.

I did find a couple master's theses that have some data (but over a
very small frequency range around 7MHz) because they used a ham rig as
a source for a bridge scheme of some sort.

Just happened to be a data sheet I have handy... As you say, others
have more data.
(for large signals, no less)

Those are actually large signal parameters.. that's a 150V transistor
running at several amps drain current.

Again, it just happens to be a datasheet I had laying around.

Substantially, as in Output C being off by a factor of more than 2.
But that could also be packaging effects, which are easier to quantify
by experiment than analysis. That's what breadboards are all about.

I would imagine that for parts used in amateur radios, this is all
thoroughly thrashed out, and there would be no big surprises. Just
that the "as implemented" data isn't readily available in 10 minutes
of searching.

> >No simple transformer is going to make that look like a constant 50

Hmm depends on what sort of accuracy you want in your impedance
measurment, eh? If all you care about is 15-20% accuracy, a pretty
big variation will be ok.

>

I never said it was unknowable. I said it wasn't readily available or
known. Clearly one can measure it, and then know it. And now we do,
at least to 1 sig fig sorts of accuracies.. which is better than we
were 24 hours ago.

and others
> state it was immaterial. It gives me pause to have given a concrete

Immaterial in the usual amateur application (feeding a tuner which
feeds a transmission line which feeds an antenna).. not immaterial
when using the tuner to measure Z.

>

> >fall into that category?
> >It's not a published spec
>
> You mean you haven't read the spec.

--- Hmm. don't see any tolerance on the output impedance spec on my
IC-7000.. page 150 of the manual: Specifications.
All it says is:
Antenna Connector: SO-239x2/50 ohm.

Page 11, where it describes the back panel
Antenna Connector [ANT1][ANT2} Accepts a 50 ohm antenna with a PL-259
connector.

Page 15, provides a recomendation that the load impedance have a SWR
<1.5:1, and a boxed warning that at SWR higher than approximately
2.0:1 it drops power.

The service manual isn't much better, although it does have a
calibration procedure for the built in SWR meter, where you attach a
50 ohm dummy load and set to SWR=1, and then 100 ohms and set SWR=2.
That just calibrates the meter, though, it doesn't imply that the
actual output impedance is 50 ohms.

 I have seen this objection too.

At least they do some measurements and they publish their results.

They do measure efficiency, in a round about way (e.g. they measure
output power into a dummy load and they measure DC input power).

Are you familiar with the the equation e=mc^2?
It is the equation that illustrates the equivalence
of mass and energy. Energy can be converted to mass
and mass can be converted to energy.

The transmitter driving the radiator increases the
energy=mass*c^2 of the radiator. What choice does the
radiator have except to release that extra acquired
energy=mass*c^2? If it didn't release it as radiation,
what would happen?

Exactly true, but Bremsstrahlung radiation also has
nothing to do with free electrons in a conductor which
are the source of the radiation from the antenna. You
might as well have said "Exactly true, but tomorrow is
June 6".

Any round about reports of achieving better than a traditional conjugate matched 50% efficiency for CW? My Drake so qualifies at probably 60-70% (250W input with approx 30W for non-amp circuitry). Does a thirty year old design still represent the hallmark of modern performance? (Actually, I consider the Drake spec as being overly optimistic, but there you are. Too many would feel cheated for CW not to tip efficiency at a higher premium.)

And imagine again that internal resistance just sizzling several pounds of heat sink with all those immaterial (ephemeral?) calories.

Interesting aproach Cecil, but matter and energy cannot be created or
destroyed which confuses what you stated!
With respect to free electrons that " may " reside inside matter,
surely you are aware that
current flows on the surface and therefore would not come in contact
with free electrons,
at least to my mind.
Unbound electrons are totally different as they reside upon the
surface which then allows for possible levitation. Either way, using
"mc sqd" the way you are implies loss of matter from the radiator. Now
this can happen with the onslaught of temperature where the matter
vaporizes into a gas as with a light bulb where gas is state of
matter, thus the filament becomes lighter. This does not happen with a
radiator of normal temperature. This is my opinion of course and you
have yours which is part and parcel of debate. This is what I enjoy.

Just measured the SWR using mfj 259b where it measures 2:1@2 Mhz with
slight variences as the frequency increases. The meter only goes to
175 Mhz so I cannot measure further. How ever the varience is ever
decreasing so I would say in the Ghz range it should be linear at
something less than 2:1 So a normal transmitter will not require an
external tuner as frequencies are scanned. Real neat. Weight is in
the order of 6.5 lbs and a weather balloon is capable of lifting 7 lbs
so that is something to contemplate this summer for top band. Have the
tilt set for approx 6 degrees which puts me above ground clutter and
will leave it there to get some experience on different bands and
conditions.

Free electrons are in the outside shells. The outside
shells are on the surface of the conductor. Only the
free electrons close to the surface of the conductor
are involved in the skin effect.

As far as m=e/c^2 mass loss due to radiation is concerned,
during steady-state, the RF source is supplying exactly
that same amount of m=e/c^2 per unit time at the feedpoint.

So why haven't you already used it on 160, 80/75, 60, 40, 20, 17, 15,
12, 10, 6, or 2 and told use about your results?

I am quite anxious to hear how well this works, because if it works
well, I will be one of the first to make one.

Please include signal reports from the station you work as well as
signal reports concerning other stations they work.

A very good frequency to try this on would be 14.300, as they are quite
good net control operators. If you work one of the 14.300 net controls,
please include their callsign and the time you worked them.

Then where do you think these free electrons come from?
Skin effect is displacement current which is surface and below
oriented
and "free" or unbound electrons are on the surface and above oriented.
This use of m=e/c sqd seems to be going over the top with respect to
radiation.

Tom, I do not work for you and I am not in your employ. When and if I
publish it you can try to make it, but for why? It is just a miracle
in my own mind! You are one of the few that have decided that
experimenting is only for those weak in mind where-as you can predict
all results while lounging on a sofa. I suppose because I still
experiment I have not reached
your advanced stage of brain power where all is known and results are
predictable.

In other words, your antenna doesn't work.

Just as I suspected.

It is just a miracle in my own mind. Just as you suspected or deduced.
But then again what does "work" mean? All antennas "work" whether you
want it to or not. But..... I have an antenna that does not "work" the
way you say it "should" work, just as you predicted!

Hi Jim,

It is described as a 24VDC design. The description in the report of negative feed back is in fact compensation, not negative feedback. The data clearly reveals its lack.

The means of rigorously enforcing an uniform presentation of output Z across loads, frequency, drive, power supply sag (what have you) would appear through the usage of negative feedback. However, as this would be a very costly addition, it is found no where except in premium designs. Total RF gain in the typical finals deck is not particularly great, so there is very little latitude for this in conventional designs. If there were, there would be no need for LPF in the output, and you could tailor the output Z to any of a multitude of reasonable values (say from 10 Ohms to 200 Ohms) on-the-fly that would further obviate the need for a tuner.

Tuners and LPFs are cheaper, however.

Look once more on the original Hertz apparatus.
In the centre the sparks (electrons) jump with the high velocity. They
oscillate. Where is the maximum deceleration?

"It is possible to create either horizontally or vertically polarized radiation with a large loop antenna. The polarization is determined by the location of the feed point as shown below. If the feed point is in a horizontal side of the loop, the polarization is horizontal. If the feed point is in a vertical side of the loop, the polarization is vertical."

For me the LARGE loop antenna is also a dipole with the two ends. It radiates from the ends the coupled electric waves.

But what radiate 1/4 wave antenna (mast) with the one end only? Is the radiation polarized?

well, your mind is wrong. it doesn't flow 'on the surface' it flows in the metal with higher current near the surface and exponentially decreasing as it moves in toward the center of the conductor... but all the current IS the result of moving the free electrons IN the metal.

>Unbound electrons are totally different as they reside upon the

That is not strictly correct. Maxwell accounted for all forces to
determine maximum efficiency. Ferro magnetic materials have a
hysteresus effect or energy loss compared to diamagnetic materials so
the former does work but not with the efficiencies of the latter.
As far as solar is concerned it is these abnormalities or disturbances
which preceed all
major radio activities thus there is a bond between these observances
that cannot be denied. The Sun is within a boundary that fractures all
the time because of temperature increase and thus expells matter. It
would seem reasonable that such matter finds its way to Earth to
settle thus giving a connection between the arrival of external
particles or electrons as opposed to free electrons that exist in
place.
As for levitation is concerned that has been known for a long time and
is presently used in Industry in many places by the introduction of
displacement current. Read up on it.
Elementary my dear Watson

S* what you are missing is the effect of spin which provides straight
line projection.
The radiation energy is released in pulses. Depending where these
pulses occur determines if there is one or two vectors of energy
applied. At the ends of the radiator which is a fraction of a
wavelength there is only one vector and thus no spin imparted.
The result of just the single pulse of energy is the spark that you
observed.

For equilibrium a full wave verticle antenna must be tipped from
vertical.
This way you do not get a pattern of a donut but a boundary that is
spherical such that the
pressure on the borders is uniform.If your vertical was arranged that
way you could trace a satellite without moving the radiator. In
defence work you would arrange your antennas in such a way so as to
avoid undetected entry via the donut hole in a vertical radiator.
That is not stupid. Equilibrium is an important factor in all
scientific laws and must be taken into account.

> Then where do you think these free electrons come from?

They are a characteristic of conductors. My physics books says the free electrons are bound to positive ions of the conductor material and (usually) cannot escape the attractive force of the metal ions. They are "free" to move from ion to ion while remaining with the conductor. The movement can be random or orderly caused by an EMF.

> ... "free" or unbound electrons are on the surface ...

Free electrons are loosely bound to atoms of conductors but they are not "free" to leave the conductor unless they are in contact with another conductor. When you hold a piece of metal, what you are "feeling" is the repulsive force between electrons.

> This use of m=e/c sqd seems to be going over the top with respect to
> radiation.

You brought it up, Art, so I explained it. Please note that if one joule per second is radiated from an antenna because one joule per second is being supplied to the antenna during steady-state, the mass supplied and lost during each second is one joule divided by the square of the speed of light which is a very small magnitude of mass.

hi "jerry"

i want QHA models and i try to adapt them for 2GHZ it's for
heliosynchron
satellite for earth sensing
thank u

Hi "disc"

Wow, thats a small Quad Helix. Tell me the dimensions. I'll try to model
it for you using EZNEC.
Is this a real project? That is, do you have the antenna, or are you
planning to build one? If you have a "store bought" 2 GHz Quad helix,
there are certainly some patterns available from the mnanufacturer. If you
plan to build the Quad helix, are you able to make any impedance
measurements of the model?
```

As you know, the fundamental plan in the Quad Helix design is to make one loop radiate 90 degrees later than the other due to the impedance difference between the two loops.

The electrons are essentially oscillating back and
forth within a few micrometers of their center positions
under the influence of RF source energy. The maximum
deceleration would therefore occur within a few
micrometers of the maximum current point.

The maximum current point in a center-fed 1/2WL
dipole is at the feedpoint.

Tom, he is never going to try the antenna or admit it doest work. Heck
I built the stupid thing knowing it was a dummy load and a CBer's
joke just to say I built it. (I was also very sick and bored at the
time). It doesnt work because the impedance of the antenna consist
primarily of ohmic resistance and dielectric losses. I doubt if he has
ever buit the damned thing .
Giving that the design of his antenna is a known CBers prank, I
suspect Art comes from the same place.

Unfortunately I also have known of someone else who behaves like Art.
He was truly a brillant person who repaired banks tabulating machines
back when they were all mechanical. He was brillant in more ways than
just mechanics, a true rennisance man if ever I met one. Then he had a
stroke. He latched on to this EXACT same "antenna" saying that he had

designed it even though I knew of its CB use years before he discovered it. He used to be a good family friend until I showed him his antenna did not work comparing it side by side to a simple dipole. For Arts sake I hope he truly is just a prankster. I wouldnt wish the changes I saw on the poor guy I knew on anyone.

I know I have seen the "antenna" before I knew it as a CB joke. I am pretty sure it was in my grandfathers collection of radio books which dated from the 20s to the 40s used as a dummy load.

What means "primarily"?
Is in reality an antenna which radiate unpolarized radio waves?

Jimmie
I hate to tell you but the antenna that you made was a result of
various statements where it would seem that the main object was to
proof me in error. So I gave a description of such an antenna to
satisfy the desires of my critics in the hopes that they would be
content.
That antenna is not the one I use . Sorry you went to a lot of work
for nothing.

Jimmie
In most antenna books they tell you that twisted pair wires act as a
transmission line where local signals are canceled by the opposing
wire. What they state is correct and used often on field day to
connect to a real radiator for when used in a real emergency.
But the antenna experts never brought that to the attention of readers
until you just did
which says a lot about existing antenna expertise on this newsgroup.
Seem like that some things in the ARRL books are disregarded by the
gurus!
Regards
Art

hi jerry
yes too difficult to construct such antenna
us i said, it's a project for my post graduate thesis, the idea is to
apply multidisciplinary robust design optimization algorithms to have
a good antenna for earth sensing satellite satellite (800KM altitude),
it will be a contribution for the algerian satellite alsat1-b, i'll
study the antenna from EM, mechanecal to thermo-aerodynamic and the
great problem is a structural adjusting of two QHA antennas on the
pannel facing the earth.
thank u

That you would use the term "unpolarized radio waves" shows you haven't
a clue what you are talking about.

http://en.wikipedia.org/wiki/Polarization

Art , I am proud of you. You gave a very direct, and accurate reply.
Your reply also indicates you are aware that your antenna could not

possibly function with any practical degree of efficency for the reason you just stated. Sir I must complement you on the artistry, the audacity and the tennacity of your scam, I absolutely loved it.

Jimmie

Don't get me wrong I gave it in fraustration with respect to the
gurus knowledge level and how they were judging me. I am or was an
engineer from the U.K. and I am not inferior to those educated in the
U.S. as some seem to think.A good laugh is good for the soul, a cheap
laught is good for nothing.
Regards
Art

Remember that gigahertz-level quad helixes used on satellites are usually multiturn devices. Model results for a 137-MHz, half-turn antenna scaled up to 2 GHz may not be appropriate.

There is a small amount of radiation off the ends
of an unterminated antenna that has opposite
polarization to most of the other radiation. I
would call it a *secondary* radiation effect as
opposed to the *primary* radiation effect.

it an antenna is in equilibrium then it is not radiating. radiation is by
definition a violation of equilibrium since it is the flow of energy away
from the antenna.

> Regards
> Art
Gentlemen and others
Before I depart from this subject let it be absolutely understood that
I do have a new design antenna, tho it is not of twisted wire. It does
exhibit 2 Mhz plus to ? ghz capabilities and can weigh less than 6.5
lbs if I chose to do so, as well as other properties that I have
stated.
Let it be fully understood that the nature of radiation and the
explanation of same is also correct. None of this should not be
confused with the tail of a twisted wire antenna which
came about accidently and was not an attempt to dismiss the expertise
of the gurus . Any embarrasement came about of their own choosing or
blind acceptance of what is presently stated in the books and
regurgitated by perceived experts in the field. In your own life time
you will be using such an antenna as well as the science books be
changed, so do not despair or be angry.
Best regards
Art Unwin KB9MZ.....xg (uk)

Hi All,

As this topic may appear to be magic, much less to those who take
religious exception to a source (such as your rig sitting on the
bench) exhibiting resistance (never mind the fan running on the
"heat"sink); I will expand upon the characteristics described above.

Those of you with any titles by Terman may follow along in the choir
book (others may consult the original work of H.W. Bode or H.F.
Mayer).

[heading] "Effect of Negative Feedback on Effective Output Impedance
of Amplifiers
"The output impedance of an amplifier can be defined as the
equivalent impedance that the load observes when looking back toward
the plate circuit of the final amplifier tube. The effective value of
this impedance is influenced to an important degree by the use of
negative feedback. Thus voltage feedback tends to make the output
voltage constant irrespective of load impedance: this equivalent to
decreasing the output impedance of the amplifier. In a similar
manner, current feedback tends to make the output current constant
irrespective of load impedance, and this equivalent to increasing the
effective output impedance of the amplifier."

[in my own words] In the absence of feedback, for an amplifier
condition known as being open loop (where its full gain, or open loop
gain, is available), the impedance looking back from the load in our
examples found in the link provided by Jim, and as exhibited in my own
measurements is on order of 50 Ohms. This 50 Ohms cascading back
through LPFs and through the Z transformation of the output
transformer is found to be very few Ohms intrinsic to the transistors.
Every step of your rig's design has been carefully managed to perform
these chain of transforms. One need only look at the topology of the
LPFs, calculate their individual component reactances at band center
to arrive at that 50 Ohm figure. The LPFs are symmetrical (mirrored
input and output) as they fully expect to see both a 50 Ohm source and
a 50 Ohm load. As these LPFs operate over an octave, it follows that
this 50 Ohm nominal value departs from the Z observed at the margins.
As a transmitter is not always run at rated power, it also follows

that the transistor's Z is not always presenting 50 Ohms through the output transformer. It follows that by the source's departure from 50 Ohms, the LPF in part must also suffer in performance. Given this region of departure is confined to lower Powers outside of amateur frequencies, that suffering is rarely exhibited in sparks or significant heat.

These variances do not argue
1. that your rig lacks source Z,
2. that is can never be found, or
3. that it is immaterial,
it merely acknowledges that this Z varies by the degree described. I find it remarkable that intelligent correspondents here carefully tally the lost power transfers of mismatch at the antenna, and wholly neglect the same mismatch at their preffered source of unknown Z. Where, by their astonishing claims your rig does NOT have a source Z of 50 Ohms, that there is no similar reckoning of lost power transfer with mismatch at that plane of transition.

When Jim noted that my source Z reports expressed a SWR of 1.4, it follows that this statement of mismatch also yields a reflected power at the input to the LPF that my rig absorbs and expresses in the heat sink, and this power is forever lost to the opportunity of transmitting it as RF radiation. A 30 Ohm source connected to a 50 Ohm load is NOT MATCHED. I cannot imagine how the arguement that a source of unknown Z (but definitely NOT 50 Ohms) could ever operate into a severe mismatch without considerable risk.

This, of course, begs the question: "Do you care if it is?" There are many competing agendas to rig operation, and 100W is rarely required when you unknowingly (through lost efficiencies through the chain of connections) radiate less and are happily engaged in a QSO of comfortable copy.

Putting that all aside and returning to negative feedback, some readers may find that they prefer to have a current source or a voltage source (there are advantages that go beyond matching, and efficiency). Negative feedback, as you may observe from Terman's quote above allows you to design an amplifier that exhibits ANY Z. If you had a short radiator - say a 14 foot whip used for 80M, then why would you want a transmitter with a 50 Ohm characteristic when two or three Ohms would more properly serve the lower radiation resistance?

This argues that you could as easily strip off the LPF and discard the output transformer to reach back to the Transistors' intrinsic resistance and ready ability to serve this purpose - but you would suffer horribly from the truly abysmal frequency hash that inhabits this last stage (LPFs are exceedingly necessary).

These distortion, noise, and frequency products can be reduced through negative feed back by the degree of feedback expressed as a portion of the open loop output. If you want to suppress them to one 100th, you

have to have 20dB of feedback (historically called "noise gain"). If your amplifier has only 20dB of gain, however, you have a net gain of 1, and your amp will now only source 1W. Terman explains this all at greater length.

How do you achieve 100W with one 100th the distortion, noise, and frequency products? Obviously you need 20dB more gain! This isn't going to be cheap to achieve your new Half Ohm source for your 14 foot 80M radiator.

If we invert the design goal to apply to a 5000 Ohm antenna, and design for a 5000 Ohm source from the rig on our bench, we will require a similar investment in that same 20dB negative feedback which, in turn, demands 20dB more stage gain.

Yes, I can imagine the multitude's eyes rolling collectively here (or the murmurs of suppress yawns). Let's go through the other benefits of employing negative feedback to the tune of 20dB:

Amplitude distortion:
who wants studio quality audio?

Harmonic distortion:
whose baritone comes out with Mickey Mouse highlights?

Higher stability:
ever have the rig trip out into self-oscillation?

Power Supply independence:
HiFi in the tube days could tolerate more hum from cheaper unfiltered supplies.

Load stability:
what happens when you forget to switch in the tuner or feed the wrong load?

Noise reduction:
modern rigs have a bajillion mixed oscillators that build to the eventual side band with lots of noise there and

Phase distortion:
same oscillators mixing comes with tons of this.

Linear operation:
who uses a wah-wah peddle on their transmissions, and yet give that impression to listeners?

There are other issues of finer granularity that achieve such improvements through negative feedback. You are not going to find it in your rig, and you will undoubtedly never add it yourself. Further, I seriously doubt you will go out and purchase it either. This financial barrier to entry is consequently responsible for keeping this topic out of mind (called denial), and in turn it renders the subject of source Z as one that is "immaterial" simply as a

psychological salve to the wounded ego of the wallet.

For an engineer and technician alike, source Z is very material.

278. A reasoning on coaxial cables

Newsgroup: rec.radio.amateur.antenna
Date: 2009-06-06 20:00:57 UTC
From: Antonio Vernucci <vernucci@tin.it>
Message-ID: <4a2acaf8$0$844$4fafbaef@reader5.news.tin.it>
Source record: 14990

Everyone knows that, when a coaxial cable is terminated on a pure resistance equal to the cable characteristic impedance, one will measure the same resistance value at the other end of the cable, independently of the operating frequency.

In theory, this should occur at any frequency. In practice, not all cable types behave well when frequency is very high (say above 5 or 10 GHz). But do all cables behave well when the operating frequency is instead very low? This could seem an odd question, but let me explain my point.

Going down in frequency, one should expect that all cables continue to work well, even down to DC (a cable terminated on 50 ohm will show virtually 50 ohm to a DC generator).

Now my story. I recently got a 100-foot roll of RG-179 teflon cable, same size as RG-174 though 75 ohm instead of 50. Testing the cable with an ohmeter, I realized that the DC resistance of the (very thin) inner conductor is about 25 ohm, that is about 0.8 ohm per meter!

At DC, that cable roll terminated on a 75 ohm resistor whould show 100 ohm to the generator. Going up in frequency, the cable loss will progressively increase and the resistance measured at the cable end will then progressively get closer and closer to the cable characteristic impedance, that is 75 ohm. So, one may conclude that such cable works well only above a certain frequency.

But if one takes a much shorter run of RG-179 (say a few feet), this would work well also at the very low frequencies. So the problem seems not to be with cable type, but rather with cable lenght. As a matter of fact, if we take a very very long run of RG-8, a similar problem would be experienced at the low frequencies.

Could we then conclude that, if one envisages to operate at the low frequencies, the cable lenght should not exceed a certain maximum value (that varies with the coaxial cable type)? For instance the value of such threshold length could be the value at which the inner conductor resistance is not higher than say 1/20 of the cable characteristic impedance.

hi jerry
yes too difficult to construct such antenna
us i said, it's a project for my post graduate thesis, the idea is to
apply multidisciplinary robust design optimization algorithms to have
a good antenna for earth sensing satellite satellite (800KM altitude),
it will be a contribution for the algerian satellite alsat1-b, i'll
study the antenna from EM, mechanecal to thermo-aerodynamic and the
great problem is a structural adjusting of two QHA antennas on the
pannel facing the earth.
thank u

Hi "disc'

This is getting a bit confused. I wouldnt consider the 2 GHz QHA antenna
too difficult to "construct". I'm a clumsey old guy and I think I could
build one. The big problem is the QHA is very critical to make work at 2
GHz. I would consider the QHA to be a poor choice for receiving satellite
signals from Earth. I am open to any discussion related to why I dont
recommend Quad Helix for reception of satellite signals from Earth.
Secondly, I assummed that "earth sensing" meant that the Quad Helix would
be on the Earth, sensing, the orbiting satellite. But, evidently, the
antenna you are investigating is to be located on an the satellite which
orbits the Earth, and there is no need to actually build one. The Quad
Helix could be a very desireable package for satellite mounted situations.

I jumped into this thread before I understood the problem. You probably
do need a complex modeling program to evaluate the radiation from the
antenna and the effects of the structure it is mounted on. The satellite
antenna will need only about 120 degree beamwidth to cover the Earth from
800 KM altitude. It is probably unnecessary for you to ever develop a
working model of the antenna. If you ever get the point where it is

necessary to know more about the Quad Helix, feel free to contact me for any discussion of hemispheric coverage CP antennas. I recognize that you may already know more about the Quad helix design concept that *I* do. I only meant to invite conversation based in facts and mild math.
If you want to model more than one Quad helix over a simple platform, EZNEC will do a great job for you. I consider the EZNEC a low cost tool that will be useful for a long time for many other "HAM" projects.

Hi Rich

Your comment helps. I wasnt aware that multiturn Quad Helix antennas
were used on satellites. can you point me to a site where the multiturn
Quad Helix is used for satellite application?

Thanks
Jerry KD6JDJ

No. The issue is that the simple transmission line theory you implicitly refer to holds for lossless lines only. If losses, either as ohmic losses in conductors and/or dielectric losses, are present, the line characteristic impedance Z0 is not constant nor real. It breaks up to be a complex number. You will have to apply the general transmission line theory for lossy lines.

As you suggest, the lossless line theory will hold with some approximation for slightly lossy lines.

> from the antenna.

I see where you are coming from David as a pendulum can be considered
in equilibrium when in a state of rest and time has not been added.
When a time varying field is added then you do have energy or flux
passing thru a boundary and the boundary has to re adjust
to establish equilibrium again, it is this change of energy that must
be accounted for as per Maxwell. Movement alone within a boundary does
not break equilibrium, only movement thru the boundary that fractures
same. Look at the boundary as an equal sign, what is lost to the
inside of a boundary is gained by that on the outside of the boundary.
From this observation you can see that energy or matter cannot be
created or destroyed even tho it may change its appearance. To
determine what is lost is to determine how long it takes for the
boundary to correct its borders. Since the action is repetitive we can
use this as the basic of time accurately and it is that of a single
"period" in time. This period length is a full wavelength, not a 1/4
or 1/2 or even a 5/8 wavelength and as yet resonance has not even
entered the picture, because we only know that repartition begins at
the point of one period where energy is placed into a radiator which
then expends that energy by the time the period end comes about. Now
you should be able to see the similarity to a tank circuit
where the period is broken up into two parts of unknown length,time it
receives energy and then the time to expend the energy. Then
repartition occurs. Now somebody in the past determined that these two
times was exactly equal, for why I do not know. For instance, the
first application of energy has the characteristic of overshoot, the
release of energy for radiation purposes is not its equal, thus
choosing the apparent resonant point as 1/2 a WL was a gigantic error
that lasts to the present day. Sooner or later that has to change or
be corrected
As must the "wave" tag which is a description parleyed by somebody as
a wave to the rotation of a particle containing a charge which has
been accelerated from the rest position

by an impact equal to that of the speed of light which actually was determined from a different source. So now we come to the subject of light which then was also determined as a wave contrary to how Newton viewed it. Now one can see that the particle of charge
is the generator of the speed of light from the initial action of displacement current and thus if momentum of the particle is changed the variation of speed between light and the particle is zero, just the change of spin has changed.
Here endeth the first lesson in Classical Physics which may or may not make it into the books of the ARRL
Art
and enlarged upon by Planck, a friend of Einstein.

Agreed, but then why the manufacturers describe the RG-179 (which has an ohmic loss of 0.8-ohm/meter neglecting the braid loss) as a "75-ohm coaxial cable"?

Exactly. Look at what constitutes a transmission line such as
resistance, G, capacitance, spacing of wires and whether the
dielectric is homogenous. Even Richard could not make or measure the
characteristics of a transmission line by comparing continuity between
every 1/1000 " of length for a the whole length of a transmission line
including straightness
when measured or the varience of proximetry effects or even the
angular movement of a S meter indicator when an imperfection is
encountered. Sometime S meters are there just to
make operators feel good.

Zo is purely resistive *only* for distortionless lines, and lossless lines are a special case of distortionless lines.

We often make an assumption that practical lines are lossless, and hence for instance speak of them with Zo being purely resistive, and independent of frequency.

For a practical coax, Zo at very low frequencies contains a significant capacitive reactance (eg using homogenous conductors at 1MHz, Zo=75.6-j9.3).

The effective resistance of the conductors typically varies with frequency (eg skin effects, braiding effects), and the dielectric loss varies with frequency. These combine to make Zo frequency dependent.

A further complication with skin effect is where conductors (usually the inner conductor) are plated or clad with a different metal to the core.

So, the concept that the impedance looking into an abitrary length of uniform line terminated in Zo is Zo is sound, just Zo in not necessarily real (ie purely restive) nor frequency independent.

At extreme higher frequencies, depending on the dimensions of the coax, it may operate in a higher mode. The frequency at which that happens effectively limits the upper frequency for a line. If you like, coax components are usually used at frequency below the cut-off frequency of higher (TE, TM) modes to force it to operate only in TEM mode.

Owen

Because considering R, L, G, and C at the frequencies normally used for
this cable, the ratio of ((R+jWL)/(G+jWC)) is *approximately* 75+j0.

Your 0.8ohm/meter perspective focusses on only one of the four parameters
above, so little wonder you come to a different conclusion.

Thanks, but then let me make the same question to you.

Why the manufacturers describe the RG-179 (which has an ohmic
loss of 0.8-ohm/meter neglecting the braid loss) as a "75-ohm coaxial cable"?

It is never Z0=75+j0 - it is only close unless specific
measures are taken in the manufacturing process. It may
be, e.g. 75-j0.5 ohms instead.

Agreed, but I still missing the influence of cable length. I would tend to reason in this way:

- with a short cable run, as you say the RG-179 works well at the "frequencies normally used for that cable". But also well at the very low frequencies (including DC)

- with an long cable run , the RG-179 would continue to work well (*) at the "frequencies normally used for that cable", but would work less well at the very low frequencies (as hinted in my example)

(*) because of the high cable attenuation, continuing to increase the cable length beyond a certain amount would not yield any change in the impedance seen by the generator

Agreed. They even write that the R is 75 plus / minus 3 ohm.

Anyway, it would seem to me that the presence of X=-0.5 ohm does not change much with regard to whether my reasoning makes some sense.

Manufacturing tolerance are another issue, the line has a -j component to Z because it is *lossy* and that Z0=((R+jWL)/(G+jWC))^0.5 is not purely real.

I mentioned distortionless lines in an earlier post. They are lines where Zo is real. You can see that if R=0 and G=0, Zo is real, so a lossless line (R=0 and G=0) is one case of a distortionless line.

If you live in a world of lossless line approximation, Zo is real, loss is independent of frequency, and the conductors have zero resistance (not 0.8ohm/m).

Practical coax lines are *not* distortionless lines, R is significantly large and G is very small at frequencies below GHz, and so Zo is *not* real.

If you pretend Zo is real, you are calculating results for something else, and little wonder that they do not reconcile with your back of the envelope DC calcs.

>
> Anyway, it would seem to me that the presence of X=-0.5 ohm does not
> change much with regard to whether my reasoning makes some sense.

Your "it seems to me" is not obvious to me, but that is because I have done the calcs, and when you dive into the detail, it does make a difference in a mathematical model. Run the numbes and see if your intuition is born out.

One can validate an approximation by comparing it with the exact solution, and if the error is acceptable for the purpose the approximation is valid.

However, for most practical purposes, the tolerances of product will mask very small effects.

BTW, the DC solution and the RF solution as frequency approaches zero *must* reconcile if they are both valid. But, you are using a simplified DC solution (centre conductor DC resistance only) compared to a GHz RF

view (where Xo is very small).

Hi Tony,

0.8 is a loss constant, not a loss per meter just as RG-35 has a 0.071
constant, RG-11 has a 0.203 constant, RG-6 has a 0.256 constant, RG-59
has a 0.32 constant, and RG-180 has a 0.615 constant.

Look at the expression Zo=((R+jWL)/(G+jWC))^0.5

L and C are relatively independent of frequency.

- As frequency (W) increases, the jWL and jWC terms increase
proportionately.

- R increases approximately proportionate to the square root of frequency
when skin effect if fully effective. R is significant.

- G increases proportionately to frequency, but it is a very small
magnitude, usually insignificant compared to WC below 1GHz.

It is the relationship between all these terms and frequency that
explains how a line "works" at different frequencies.

The real part of the propagation constant gamma=((R+jWL)*(G+jWC))^0.5
give the one-way attenuation characteristic, and again it is frequency
dependent.

The problem in applying this down to DC for RG179 is finding the
effective value of R at very low frequencies.

The model works, and long-line engineers have understood its application
to transmission lines down to hundreds of Hz, and they don't assume that
Zo is real. (Though 'everyone' talks about phone lines as 600 ohm lines,
they aren't!)

A lot of audio designers treat a coaxial line as having a capacitance per
unit length. This is an approximation that treats R, G, and L as zero, an
approximation that is reasonably valid at audio frequencies for a short
line when terminated in a resistive load that is much greater than Zo.

Designers calculating 12V power distribution in a vehicle might consider
(as you have) just the R term, ignoring all others as at W=0 WL and WC
are both zero and G is typically extremely small at DC, so a R only model
is a good approximation of a line at DC terminated in a very low

resistive load.

But, you cannot compare an approximation for one scenario with another scenario without considering whether the approximation is valid for both scenarios.

Your DC approximation is not valid for radio frequencies, and for that reason, you cannot compare its results at DC and at radio frequencies.

Owen

OK David so it was to much for you and you have gone over the top.
If you had taken action like I suggested you would not have separated
logic from your brain. It is going to take a long time for you to
recover so be nice to your wife as you will now need her more than
ever. Sorry to see you succumb to this fall. He who laughs last laughs
alone but you knew that before this happened.
Take care

So you think it's fine that

1) You deceive those you are debating with.

2) The antenna you really are arguing about isn't the same as what you
have described.

3) You don't need to test said "real" antenna, because it works in your
own mind.

You are so full of S--T that it's absolutely amazing.

Archive-name: radio/ham-radio/recruitment
Revision: 1.1 2007/09/29 18:42:47
Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.

Hi Clark

the 0.8 ohm per meter figure was not taken a by a catalog. It simply comes from dividing the measured DC resistance of my RG-179 cable roll (which is 25 ohm) by its length (which is 30 meters).

Are you sure that radio waves are transversal?
We are trying to find how the dipole works. The are the two possibilities:
1. Dipol radiate the Maxwell's wave from the centre,
2. The two ends radiate the two pressure-like electric waves.

What do you prefer?
S*

It is certainly very possible to build QFHs for 2GHz there are several
designs available on the web for GPS receiving applications.
I have constructed one based on semi-rigid co-ax.

A quick search on Google will bring up plenty of info. Here are just a
couple:

http://home.iae.nl/users/plundahl/antenne/helical.htm
http://www.ien.it/~brida/LNAGPS.htm

> Jerry KD6JDJ

I don't have any links for that, Jerry. I stopped doing LEO WXSAT stuff a few years ago, and even then I only had photocopies of stuff -- nothing online.

As I recall, much of the early work was done by a fellow named Kilgus. The papers I had presented analyses (predicted radiation patterns, etc.) of a wide range of quad helixes, and some had pictures of cute little multigigahertz jobs that had to have been made by a good machinist.

An Internet search for Kilgus may pop something up. But since the work was done well before the dawn of the Internet, you'll probably find mostly references to Kilgus instead of copies of his work.

Source record: 14834

I am trying to validate impedance values I am measuring with my
MFJ-259B. I attempted this by using my MFJ-993B auto tuner. The tuner
uses a simple L network to create the conjugate match. I took
the final inductance, capacitance values from the auto tuner
digital display after achieving a 1.0 swr match and back calculated
the transmission line
input impedance that the tuner is seeing. I used the RevLoad load
program (link supplied
by Roger in an earlier post) to determine Tuner Z.

For what it is worth, here is some data.

Frequency MFJ-259B Z Tuner Z (calculated)

3.5Mhz 15-j36 27-j42
3.98Mhz 34+j42 32+j28
7.15Mhz 48-j18 46+j2
14.175 Mhz 87+j0 53+j7
28.350Mhz 28-j19 65-j16

Hi Rich

Yeah, Kilgus presented papers to describe the Quad Helix to "the masses"
back in the 1968 (I think). His papers were published in profesional
fashion, and very well detailed. My understanding of the Quad Helix is far
more simple than Kilgus's.
I see the Quad Helix as two oblong loops, each twisted 180 degrees. One
loop os fed to radiate 90 degrees later than the other. The objective of the
design of a Quad Helix is to acheive a Hemispheric radiation pattern with
Circular Polarization. It would seem that "multiturn" of the Quad Helix
would defete the Hemispheric objective.

The problem many Quad Helix antenna builders have is related to the way
the 90 degree delay is acheived. Kilgus acheives the delay by controling
the feed point impedance of each "loop". That gets quite intricate for
microwave devices, as you know. A small change in configuration of the
antenna can seriously effect the impedances and therefore, the phasing. In
short, the Quad Helix is a great antenna for a satellite installation when
significant time and equipment is available for developing the antenna

design.

discretman16

Hi discreteman16

I couldnt figure out how to see the referenced sites without paying
$31.50. But, that looks like a site where extensive computer modeling has
been documented. It becomes quite obvious that I am at a far too low level
in my math and theoritical capability to assist you. I dont even know what
ANSOFT and matlab are. But, I use EZNEC to describe Quad Helix antennas
of my design. It takes me less than 10 minutes to describe a Quad Helix
in EZNEC. I strongly recommend EZNEC to any young person who has *any*
interest in designing or understanding antennas. It is a great tool for
anyone who is interested in antennas. If I can be of any help to you by
trying to model a Quad Helix for you, you are welcome to contact me.

Watch it Dave, that last statement is Gaussian and lacks the "t"
variable making it static. Getting the jump on Art and adding "t", it
becomes:
>(my knowledge about antennas will always be zero at this rate)

This added time dimension cannot be in dispute, can it? It brings
equilibrium, was proven by Newton, and thoroughly demolishes
Einstein's work in the same stroke. (Patent Pending, so it must be
true).

Hi Tony,

Then you are suffering from one of two problems:
1. Your measurement is seriously in error, or
2. Your cable is from a very poor vendor, or
3. You have reported the wrong type of coax.

All that aside, the reason why it is specified as any specific Z has
been well described. If you take issue with any "one" measurement of
R that seems to confound those descriptions, then "any" measurement of
R would do so, likewise.

In other words, ALL cables exhibit the loss of R. There are coaxial
cables that are very much smaller than yours that are employed in
transducer probes for doing ultrasound scans of patients. You would
need a microscope to measure their dimensions. And they have enormous
loss.

That you not post your babbling crap here.

Read the link I provided, then read the links it provides.

There are about 100 years of experimental measurements that say how a
dipole works, which is the entire dipole radiates.

you might want to try the mfj reading again at the coax going into the
tuner. the length of the line and the impedance lumps from the relays in
the tuner will transform the impedance going through the tuner even in
bypass mode. while the difference may be small on the low bands it could be
significant on the higher bands.

You may or may not be creating a *conjugate match*, probably not, it is unimportant. What you are doing with the tuner is adjusting it so that the network *input* impedance is 50+j0 or VSWR(50)=1.

Think about it.

I am not surprised, in fact, I would have been surprised if you got good agreement.

You have two many unknowns. Do you have something that is known, like a good dummy load, a good VSWR meter? Check that the VSWR meter reads 1:1 n the 50 ohm load. Then, if you adjust the tuner with a known 50 ohm load and a known 50 ohm VSWR meter, do the tuner settings reconcile with your expectations?

This experiment might give you some feeling for the scope of error using the method.

Owen

Thanks Dave. I completely missed that. New data set follows with
transmission line directly connected to MFJ-259B. Maybe a little
better agreement, but still too many variables and uncertainties in
the instruments I have to expect much better. Owen, Cecil, Richard et.
al. pointed this out when I started down this trail. Still, it was a
good exercise and I learned some things along the way

Look at http://hongsencables.hisupplier.com/product-190292-PTFE-Cable.html and you will see that the RG-179 cable has a Direct Current Resistance (DCR) of 800 ohm / kilometer, that is 0.8 ohm per meter, exactly what I measured. That is the normal resistance value for a 7-wire stranded copperclad conductor, each wire having a 0.1 mm diameter.

Should you think that the Chinese firms are poor vendors, then read the characteristics of the US-made RG-179 built by Belden on http://us.100y.com.tw/pdf_file/Belden%2083264.pdf, where they report a resistance of 244 ohm per 1000 feet, that again corresponds to 0.8 ohm meter.

Regards

Tony

335. FT-857, FC-40 and the AM Broadcast Band

Newsgroup: rec.radio.amateur.antenna
Date: 2009-06-07 22:32:35 UTC
From: "Bob D." <bobbyd849@comcast.net>
Message-ID: <VOWdnVpO7tZForHXnZ2dnUVZ_jGdnZ2d@giganews.com>
Source record: 14847

I just installed a Yaesu FT-857 with the FC-40 tuner and a 102 inch whip in my car. The system is working well but there are two "annoyances":

1) I like to listen to AM broadcast occasionally. Although the transceiver will tune the broadcast band, the whip is too short for this band. AM reception is very poor. Is there any way to get the FC-40 tuner to help? If the tuner would just kick in some inductance, it might help. (I imagine shortwave broadcasts have the same problem.)

2) The FC-40 seems to default to "straight-through" when you tune to a frequency segment it has never tuned before. When tuning through the 60, 40 or 20 meter bands the receiver "falls off the cliff" when leaving a previously-tuned segment and entering a new segment. The S-meter drops to S zero, and I have to push the ANT button to get reception back. This is annoying to say the least. Why doesn't the tuner retain it's match, at least during receive mode?

Hi Bob

If you want an interesting project, I'd suggest that you build an AM
Loop antenna.

OK. Then you need to consider that the line is transforming the load Z to the Z measured (by both methods) at the line input. I realize you already appreciate this. However, the length of the line in wavelengths also casts more exaggerated results into your computation when that length is not a multiple of odd eighth wavelengths. This suggestion comes from Walt Maxwell's own work and sidenotes to his measurements as published in any of his several releases of "Reflections." Read his commentary on this for more detail.

When you said "At the load" I thought you meant at the antenna. When you said "through the line" I thought you meant at the line input (source end). I am measuring at the line input (source end) with both methods. Are you saying that line length could be a factor in the quality of the line input impedance measurements?

Thanks. Still learning here.

First thanks for the many replies to posts I make here. I enjoy the dialogue and am fortunate to have access to the knowledge and experience here.

Other than my MFJ-259B and my DMM, the only other piece of test equipment I have is an oscilloscope. Would it be possible to wrap several turns of light gauge enameled wire around the jacket of the coax at my operating position, attach the oscope probes and detect and possibly measure the amplitude of any common mode currents?

Do you understand that the common mode current is a standing wave. What if you measured it at only one location, and that happened to be a deep minimum... what would that tell you?

Yes, but I am specifically interested in what's going on near my
operating position. Have had some problems with computer peripherals
when transmitting on 80m.

This may be a better way of going about it:

http://techdoc.kvindesland.no/radio/ymse1/20061216153319205.pdf

I know I could just wind chokes to try and eliminate any common mode
rf at my operating position. I just like the idea of measuring first
to see how effective the chokes are.

That will work, but here's a way to make an actual quantitative measurement, assuming the bandwidth of your 'scope is at least a few times the highest frequency you want to measure:

1. Find a ferrite core large enough to fit over the coax and connector. Common type 43 is fine, or any of the lower frequency ferrites (e.g., Fair-Rite/Amidon 70 series) if you're measuring at HF.
2. Wind 10 turns (10 passes through the core) of enameled wire on the core. Connect a 100 ohm resistor across the winding with leads as short as possible.
3. Slide the core over the coax. Measure the voltage across the resistor with the 'scope. The common mode current in amperes = 10 * the 'scope voltage(*).

(*) The current through the resistor is 1/10 the common mode current due to the 1:10 turns ratio. The voltage across the resistor is i * R = 1/10 the common mode current * 100 = 10 * the common mode current. The transformer will look like a one ohm series resistance (R / N^2, where N is the turns ratio of 10) to the common mode current.

Well, doing is learning.

My own view is that common mode current meters are seen as a magic
bullet. It is true that if you make a single measurement and you observe
substantial current (meaning you have some absolute calibration), then
you know there is a problem.

The problem is that if you don't observe current in that single
measurement, you cannot infer that there is not a common mode current
problem.

Some things that you might do may just move the standing wave pattern.
Again, measurements at a single point are a very limited perspective.

The best countermeasure is design of antenna *systems* for low common
mode current.

Nevertheless, we need to make some compromises on suburban blocks and
physical symmetry can be one of the sacrifices.

Take a leaf from the books of lightning protection. They usually firstly
try to shunt the undesired current to ground rather than trying to impede
its flow through the equipment room.

If that isn't enough, then impede its flow into the equipment room so
that more of it is shunted via the ground path.

Very much.

>Thanks. Still learning here.

If you were to observe your line distance from the measurement out to the load, and plot that, you want the line distance to the load to be some odd-eighth interval of a wavelength long (1/8ths, 3/8ths, 5/8ths, 7/8ths, ... and so on). The reason being that your load Z will be transformed through that odd eighth to a region on the Smith Chart that has a milder shift in reactances and resistances for a slight change in frequency. This means errors of line-length contribution have a reduced impact on that transform. If you were in quarter wavelength relationships, those chart lines of reactance and resistance would change far faster for the same errors in line-length determination.

In S15.3, Walt lays out a method of characterising a length of line used for measurement, and then using the characterisation, to refer measurments of a load at the line input to the load end of the line.

TLLC at http://www.vk1od.net/calc/tl/tllc.php will perform the second part of that using published line characteristics.

A quick check shows that TLLC produces very similar results when the VSWR is low, and less so at the end of the data range where the VSWR is 10. Reasons for that include that Walt used a characterisation of the cable used for measurement, and those characteristics are not exactly the same as published spec, and Walt's calculation engine makes some approximations that are not made in TLLC.

The discussion highlights that the method is only as good as knowledge of the coax characteristics, and the accuracy of the measurement instrument. Errors will be worst when the line operates at high VSWR.

I would argue that if you use an MFJ259B, for measured values that are not near the limits of the instrument, and |arg(Z)|<70°, you will get relatively good results from TLLC. Validating the length and loss of the measurement coax to ensure it complies with spec is a precursor to using TLLC with best accuracy.

I am not interesting in theoretical physics.
>
> There are about 100 years of experimental measurements that say how a
> dipole works, which is the entire dipole radiates.

In the last 100 years the experimental measurements show that the feed line (the two wires where something oscillate) do not radiate and that the two bended ends radiate. This ends you call "entire dipole". Todays dipoles are simply the two coupled monopoles.

The only one really dipole was the original Hertz apparatus. There no feed line. There is the discharging of capacitor which is charged from tiet to time. Se:
http://people.seas.harvard.edu/~jones/cscie129/nu_lectures/lecture6/hertz/Hertz_exp.html

There is wrote: "According to theory, if electromagnetic waves were spreading from the oscillator sparks..."
The oscillator sparks are in the centre. At the ends are the capacitor plates. What radiates? The sparks or the plates?

Experiments show that radiation from the original Hertz dipole and from todays two coupled monopoles are polarized. (in sense that the receiver antennas work better if are parallel to the dipole).

Now portable radios and many others aplications work in each orientations.
My question is simple: What type of emmiting antennas are used in such applications?
Are they monopoles?

So I do the next approach:
Some antennas (emitting and receiving) work better if they are parallel.
Sometimes "the polarization is not that important. Your
cell phone and indoor WIFI are examples." (Wim).
What emitting antennas are used in the applications where "the polarization
is not that important"?

Thanks for the free English lesson.

My knowledge increases a little after yours:

"Actually you have mixed up two different characteristics. Polarity
and polarization are NOT the same thing. With RF radiation, the wave
is constantly changing polarity (that is why the source of RF is
called alternating current), but within the "line of sight" of the
antenna, the polarization for a dipole is defined by its angle to the
earth as viewed by the observer.

If you see an horizontal dipole, it produces alternating polarities of
waves with horizontal polarization. If you see a vertical dipole, it
produces alternating polarities of waves with vertical polarization.

RF energy is ALWAYS changing polarity."

My knowledge will be full if you write something about the monopoles.

Source record: 14765

Maybe some people can take something away from my unfortunate experience.

Wanting something to use on occasions where I don't want to install my Bugcatcher, but would still like to do a little HF, I went to a Hamfest Sunday and picked up a 20 meter Hamstick and a big honkin' mag mount for it.

Installation was pretty straightforward. I installed it in the parking lot, tuned it up and set off home. Most of the way it was just FB. It wasn't the bugcatcher, but I knew that going in.

Traveling over the Alleghenies, there is an area where there are some fair sized gusts of wind. I hit this on the downhill side of the last mountain rage heading into the valley near home.

I was traveling about 65 mph, when a gust of wind came along, ripped the antenna and mount off the roof. The exit for the coax is on the back door. As the antenna and mount traveled backwards, the cable held it in position, so it swung in an arc and hit the rear window of my Vitara.

Ouch.

The glass of rear windows is different than that of front windows. It is designed to granulate instead of hold together. It looks pretty cool in fact. The sudden opacity of the glass radiating from the spot of impact, then everything disintegrating and falling into the back of the vehicle.

But the visual interest does not make up for the fact that now I have an expensive mess to clean up.

NO more frickin' magnets! PTUI!

There are lots of alternate sources for USENET, some free.

Here's a nice free one:

http://www.motzarella.org/

news.motzarella.org is a private project providing free access
to text-only Usenet News. The server has a 100MBit connection to
several Internet backbones and is integrated into the Usenet via
more than 60 peers.

As bad as that experience was, it could have been worse. If the coax had come loose, it could have broken the windshield of or caused other damage to a following car.

I had a 5/8 wave 2 meter whip come loose once. It stayed connected and bounced along behind the car for a while -- luckily no damage except to the whip. I've used only 1/4 wave 2 meter whips since.

My provider, Comcast, also dropped the Usenet service a while back. I signed up with Giganews.com to continue the service. There are many companies that offer Usenet at a nominal fee.

Internet service providers are claiming that the Usenet is no longer popular. (Notice that their fees do not drop when they drop Usenet.) Sure, there are lots of Web based forums. But, there is no central location to find a forum. Also, they all work differently and make you jump through sign-up hoops (sometimes demanding too much personal information!).

Your experience is exactly why I've been afraid to mount an
antenna on my newest car. It never fails.. @#$% happens!!!
And when it does, it's often ugly.
I've also been afraid of mag mounts even though that is a
possible way to get on HF from a small car.
But they can get knocked off, and I'm also afraid that I
could cause sheet metal damage just pulling some of
the larger ones off the car.
So anyway, I've had that car over two years now, and I
still don't have a radio in it.
That is very unusual for me, but I hate dents, scratches, etc
on a car that doesn't have any yet..
I still have two radioactive trucks if I really feel the need to
talk. :/

Nothing to attach one to unless you installed
some kind of frame underneath the rear of the car.
There is nothing underneath except the bottom
of the trunk floor if I remember right.
But even if I could mount a hitch mount, I'm not
sure how happy I would be with it.
Generally, that's about as bad a place to mount
an antenna as you can find.
The one method I might consider would be a trunk
lip mount. And even that makes me paranoid as
I'm worried the stress of the antenna whipping
back and forth will warp the trunk lid after a
period of time. The metal is pretty thin on that car.
"Toyota Corolla".
I've just been taking my radio with me, and using
the antenna's I have at the site.
But now even more great news.. :(My 706mk2g
has been acting squirrely. 440 went out on it,
and I think the band switching diodes or transisters
blew up. I used it a while with no 440 and was
ok, but now it's acting weird, locking up, etc..
So it's sick and is gonna have to visit the radio doc.
I don't think I want to mess with it. I've fixed most
my own rigs in the past, but I don't think I want to
mess with that thing. So I'm gonna send it off.
I need to find me another HF mobile backup rig...
The 706 is the only 12v HF rig I've got right now.
Well.. I do have an old IC 730, but the display
board is out.

You can get a "light duty" receiver for almost any car (used to hold bike racks and the like). I was going to go that route for my BMW 325, but after looking at the design, I built my own.. A piece of 1x1 square tubing bolted to the bottom of the spare tire well (this is what the trailer hitch bolted to). Drilled two 3/8" holes in the bottom of the well to bolt it on.

Then, the antenna mounts on bracket made of the nesting square tubing (e.g. 3/4") and there's a 1/4" pin that holds it in. I just slid the 3/4" tubing in and drilled both together (guaranteed registration of the holes!)..

The 3/4" tube (which is roughly horizontal) is joined to another vertical piece of tubing, to which a SGC tuner and the 9-10 ft whip is attached.

http://home.earthlink.net/~w6rmk/mobile.htm

Why not use the trailer hitch? Because when I called around to buy one, nobody local had one in stock, and I was motivated to "get it done today"..

I use a Comet trunklip mount for the VHF/UHF whip. If you adjust the angle right, it clears the roof of the car when you open the trunk.

The possibility of common-mode current on the outside of the braid has
been mentioned, but nothing has been mentioned concerning whether a
balun is used if the feedline-antenna connections is unbal to bal. If
there is no balun where should be one, seems to me it's a no-brainer
that the problem is common-mode current causing the different SWR
readings with different lengths of feedline.

I have had a couple negative experiences with single magnets, and one with a 6 meter halo on a triple magnet. I would say the triple or quad with a hamstick is practically impossible to knock off, however. At least at any speed less than 30 over the interstate limit including normal wind gusts. Or so I've heard.

One other thing you need to consider about magnet mounts is that a layer of water will end up underneath the magnet due to imperfections in it and the roof. You _will_ damage the paint if you leave it on for more than a few days at a time. You _will_ damage your paint if you put it on and remove it regularly to get rid of the water. It's a Catch-22.

I have created a tutorial to explain decibels. It is located here:

http://www.fourier-series.com/rf-concepts/decibels.html

It consists of a flash program that allows user interaction and also
contains a fair amount of embedded audio explanations. The flash
tutorial is about 7M , most of which is the embedded audio.

377. Electromagnetic wave question

Newsgroup: rec.radio.amateur.antenna
Date: 2009-06-09 09:01:43 UTC
From: Peter <colleenpeter@westnet.com.au>
Message-ID: <C4udnQrCK6JkubPXnZ2dnUVZ8vqdnZ2d@westnet.com.au>
Source record: 14789

In the electric power industry there is increasing public concern regarding fields around power lines. The general public often refers to these fields as electromagnetic radiation, which it is not. We generally are concerned with magnetic fields and less often with the electric charge fields. The two are treated as separate issues.

I believe the same is true of antennas, that is the electric and magnetic fields are separate when you are close in to the antenna in terms of wave-length.

Question:

If this assumption is correct at what point or distance do the two relatively independent fields become the one all important electromagnetic wave?

Hello Peter,

The point where the fields merge to the EM wave depends on various
things.

There are three field zones used within the antenna community:

1. The far field zone (Fraunhofer region), where there is a true
spherical wave behavior, and the radiation pattern of the antenna is
independent of the distance to the antenna. The antenna can be treated
as a true point source emitting EM waves. The far field zone is mostly
taken r > 2*b^2/lambda, where b is the largest size of the antenna.
This formula is very conservative. Depending on the current or
aperture distribution, the far field can start from r > 0.5*b^2/
lambda. E- and H- field is proportional with 1/r (r=distance).

2. The transition field zone (Fresnel region), where the fields have a
reasonable wave character, but are not spherical. The radiation
pattern of the antenna depends on the measuring distance. This one is
tricky. An antenna with a null in the far field pattern may show
significant radiation (in same direction) in the transition field. So
within the transition field, you cannot for sure assess field strength
levels based on the far field radiation pattern. Also the main lobe
in the far field pattern may not be the main lobe in the radiation
pattern measured at distance far below the far field distance. You can

compare that with coherent light passing through a round aperture, you get an onion shaped ring pattern on the wall (airy disk). You can even get a black hole in the center at certain distance. So here field is not proportional with 1/r.

3. The reactive field zone. This is the region where you can calculate the fields using electrostatics and induction. In many cases, fields are 90 degrees out of (time) phase. r<0.16*lambda is used frequently. Of course, there is no hard distance where the reactive field zone stops and the transition field starts. The decay of the H and E field are different depending on the antenna and the orientation of the antenna.

For small loop antennas, r > diameter AND r<0.16*lambda, H field decay is proportional with 1/r^3.

Another example is a HW dipole. It does not radiate on the axis of the dipole. But when you are at (for example) 0.5*lambda from the ends (but on the axis), you will sure measure an E-field (because of the reactive fields that decay with r^3 to r^2).

Another example is the field between a wide parallel strip transmission line that is well terminated (strips face each other)…. Both E and H are virtually homogenous between the strips, are in time phase and are spatially 90 degrees out of phase. So there is a plane EM wave traveling between the strips (no reactive issues).

The situation becomes more complicated when interaction with other materials is present also (for example reflection on metal sheet). You can have points where you have only E, but no H, and vice versa. This is comparable with reflection in a transmission line.

Sorry for the long text, but I hope it is useful.

Best regards,

Wim

I have a 5/8th also. There is a bridge on the local interstate where a lot of pigeons live. They seem to like to play "chicken" with the cars. One day a couple flew really close while I was driving by. One of them swooped up, missing the windshield, but unfortunately finding my 2 meter antenna. All I could see in the rear view was a lot of feathers. The antenna stayed put. Bent it a little though.

Hi discreteman16

I appreciate the fact that you could be surprized about my ignoirance.
But, I am an old "handyman" kind of guy who likes to play with antennas.
The last time I worked as an antenna design engineer was in 1969.

I'd be happy to assist you with simple antenna modeling with EZNEC.
There are very few EZNEC users who know less about antenna modeling than I
do. It is my belief that 'if I can learn EZNEC, anyone can'.

If you intend to model a Quad Helix with EZNEC, it is necessary to
purchase the version that configures a helix with a "stroke of the
keyboard".

Send me the dimensions and frequency of your Quad Helix and I'll model it
for you. I'll try to keep a record of the time required.

Jerry KD6JDJ

It is perhaps that "normal" business that is where the problem lies.
This road (speciifically, it is route 22 over Cresson mountain near
Altoona PA, is notorious for high and gusty winds. They have wind
warning signs, and even a tower mounted sensor that will trip electronic
signs. Trailers have flipped over in that area. Who knows what exact
wind hit me.

hi jerry

frequency = 2025-2110 MHz uplink or 2200 -2290 MHz downlink
number of turns = usually 2
radius = 1 to 3 inch

good luck for therecord and thank u

388. Re: Decibel tutorial

Actually we don't even have to remember 1.6 to get the numbers in Step 4, we can derive it from previous steps:

Step 2 gave us 9dBm=8mW and Step 3 gave us 7dBm=5mW. So 2dB (9-7) must be a power ratio of 8/5=1.6

If this means a disconnection for me, I may need to find a new ISP. It seems I pay a lot for services like this. What are the rest of you doing?

The following message was apparently posted locally to those of us who pay sbcglobal.net - -

news-support@sbcglobal.net wrote:

That is a great thought. Thanks for the insight. I'll stick with the
1.6 number in the tutorial though.

hi jerry

frequency = 2025-2110 MHz uplink or 2200 -2290 MHz downlink
number of turns = usually 2
radius = 1 to 3 inch

good luck for therecord and thank u

Hi disc

I made a first approximation of a 2.2 GHz Quad Helix. It came out as a
2.274 GHz Quad Helix. It is about 40 mm tall and 20 mm wide. It took me

about 45 minutes mainly because I chased a few mistakes.

Contact me again via my E-mail for any additional info. Tell me what wire diameter you prefer.

I had difficulty trying to open the file you sent. My computer skills are really poor.

Jerry

by "electromagnetic wave" you really mean freely propagating wave... and
by definition it's at the point where the ratio of E/H = 377 ohms, aka
"the far field".

Closer in, the ratio between E and H may not be 377 ohms, and energy is
moving back and forth between the fields and the antenna (or between the
E and H fields, depending on your conceptual model).. a region also
called the "reactive near field" or "near field"..

Lots of folks also talk about a "transition zone" where there's both
significant propagating wave and stored energy.

None of these boundaries are hard and fast.. there's some conventions
used in connection with things like antenna ranges. The conventions are
derived from an underlying assumption that the real behavior isn't
significantly different (in a measurement sense) from what you measure.

e.g. the "far field" assumption for antenna range distance
(2*D^2/lambda) is where the deviation of the spherical wavefront from
the assumed perfectly flat is small enough that the error in the
boresight gain measurement is "small" compared to other effects. (It's
comparable to the Rayleigh criterion for optical reflectors)

The old web sites are rather interesting:
<http://web.archive.org/web/*/http://www.mediafusionllc.net>

My favorite is the photos of the interface controller built into a
wall outlet box:
<http://web.archive.org/web/20000229124801/www.mediafusionllc.net/northamerica/main/tech/interface.html>
I showed it to a friend in the power industry who had some interesting
things to say about sharing a power outlet box with phone and cable.
However, the 14 flashing lights are kinda cool.

The problem with such patents is that if someone actually invents a
decent way to couple, distribute, and switch gigabit data on the power
lines, they'll end up in court fighting this patent. This is also
known as a "blocking patent".

It's sometimes fun to see where they spend their money. In 1999, they
burned $120K on lobbying. In 2000, they only wasted $70K.
<https://www.opensecrets.org/lobby/clientsum.php?lname=Media+Fusion+LLC&id=Y00000338320&year=1999>

Also, I dunno about the FTL (faster than light) antenna design. That
implies that the acknowledgements will arrive before the
transmissions, which will surely confuse a T/R switch. Perhaps a
predictive T/R switch will help (one that switches before one intends
to switch it).

> Walt, W2DU

Hi Walt,

I have always used a good balun on all my antennas, and therefore I am not too convinced that, in my case, the SWR change I observe when adding (or removing) a piece of coax in my station could be due to RF presence on the coax braid.

Anyway, I have not yet read a clear and convincing explanation of why the presence of RF on the coax braid would cause the SWR meter to give a different reading when moving it along the line.

I appreciate that, with a hot braid, the coax cable becomes part of the antenna and then radiates, but I cannot clearly focus why this can cause the SWR meter to see different impedances at different points of the line. Impedance is the ratio between RF voltage (between center conductor and braid) and (differential mode) RF current. So, I do not well visualize how the presence of a common mode RF current can influence the meter reading.

Why are you using a 4:1 balun with a dipole ? If it is a simple dipole with only one wire in each direction instead of a folded dipole the impedance is around 70 ohms. If you decide on a balun it should be a 1:1.
When adjusted for the lowest swr you may find that 1.4 to 1 is about as low as it will go if you use a 50 ohm coax.

If you keep the same total line length and move your meter to different points along the line, current on the outside of the line won't change the indicated SWR except to the extent that the SWR meter is poorly shielded and affected by the current. However, I believe the problem was stated in such a way that the SWR was seen to change as line was added or removed, that is, as the line length changed. And that could change the actual line SWR for the reason you described.

Perhaps you should set aside your confidence that there is no common mode current, and do some experiments with shielded loads and coax lines.

For example, you could parallel two 50 ohm loads at a T piece, and measure the VSWR into the branch line at different lengths and locations. Try it also with some sections of 75 ohm line if you have some available.

Come back and describe the experiments and results if they do not behave as expected.

If you get info fine detail about the effect of a VSWR meter calibrated for 50+j0 on a line that is not exactly 50+j0 (eg practical lines), my notes at http://www.vk1od.net/transmissionline/VSWR/displacement.htm might help you to understand what may be happening.

When you have convinced yourself about the soundness of the broad statement that for most practical cases, VSWR decreases smoothly from the load to the source, and the decrease is accounted for exactly by the line loss.

>
> Anyway, I have not yet read a clear and convincing explanation of why
> the presence of RF on the coax braid would cause the SWR meter to give
> a different reading when moving it along the line.

If you maintain the common mode current path exactly, and move the SWR meter to a different location, the VSWR should be seen to decrease smoothly from the load to the source, and the decrease is accounted for exactly by the line loss.

If you change the common mode current path in any way, you may cause a different load impedance at the far end of the coax, and that will affect the VSWR.

>
> I appreciate that, with a hot braid, the coax cable becomes part of

> cause the SWR meter to see different impedances at different points of

> the line. Impedance is the ratio between RF voltage (between center

If the VSWR>1, then the impedance varies all along the line.

The VSWR meter doesn't directly read the impedance, but it shows the VSWR, and although the impedance may vary radically, the VSWR decreases smoothly from the load to the source, and the decrease is accounted for exactly by the line loss. (I think I have said that before.)

> conductor and braid) and (differential mode) RF current. So, I do not
> well visualize how the presence of a common mode RF current can

See above and my notes.

But, while you are fixated on the belief that you have zero common mode current, what you report cannot be explained by conventional transmission line theory.

Owen

PS: "most practical cases" means the VSWR as indicated on an instrument calibrated for 50+j0 and used on low loss nominal 50 ohm line at HF or above.

Yes. Radiation is proportional to f^4. So at 50Hz practically no radiation.

> We generally are concerned with magnetic fields and less often with the
> electric charge fields. The two are treated as separate issues.

The two were seperate in ancient ages and now in the textbooks. It is the
necessary simplification.
But the adults have the two ways:
1. The way (EM theory) by Biot-Savart and Maxwell where the current create
the magnetic whirl,
2. The way by Ampere and many others where the moving charge create also
electric field. Here the magnetism is an illusion.

>
> If this assumption is correct at what point or distance do the two
> relatively independent fields become the one all important electromagnetic
> wave?

You have the answers for the way 1.
For the way 2 we have only the one electric wave. But would be easy to you
to check which way is right.

In the way 1 EM waves are radiated by the AC (current create magnetic whirl
and this create electric whirl and so on). Radiate this part of antenna
where the current is max.

In the way 2 the electric waves are radiated by the two ends of Hertz
dipole. So the dipole radiate the two coupled electric waves. The receiving
antena should detect the doubled frequency (on monopoles no such effect).
You must distinguish it from the harmonics.

Hello Antonio,

Do you have access to a 2m or 70cm set? If so, take a piece of 50 Ohms coaxial cable (of about 1m). Plug it onto your set (or a separate VSWR meter) and add a quarter wave to the other end. Do nothing with the braid at the other end.

Now select low power setting. Measure the VSWR while you move you hand along the cable. You will notice change in VSWR for sure.

The reason for this is that the QW antenna requires a good image. The image impedance is in series with the radiator impedance (simple point of view). This image is the cable, VSWR meter and set. When you change this, you will notice change in VSWR. The easiest way to change the

image/ground/counterpoise is capacitively with your hand.

Of course you may assume that you don't have common mode current (because of a balun), but best is to turn such an assumption into a fact.

Best regards,

Wim

In the late 60s I built a 40-50 foot Yagi in the attic tuned to WFMT.
I used twinlead for the driven element and wires or metal tape suspended
by string anchored to handy rafters. Over a very narrow frequency range
it had enough gain over a regular FM Yagi I could listen in stereo instead
of mono. I used the information in Orr's VHF Antenna book to get the
element lengths and spacing.

I wonder if that thing is still up in that attic - if the apartment
building is still there.

Hello, and if that's so can't you find another ISP? Even if you don't
have access to usenet, there are other non-usenet ham radio forums and
discussion groups. For a long time usenet/nntp was the only game in town
but there are plenty of alternativies out there now. Sincerely, and 73s

I guess I was thinking that if AT&T withdrew their support of usenet, it
wouldn't be long until its lack of validation (usenet) by such a famous
leader in communications would encourage more and mother smaller companies
to follow suit, eventually leading to a lack of use and accreditation,
socially.

Dittos. Radiates equally poorly in all directions though A rotatable
dipole or 2 el beam would be a simple project.

Nonsense.

The difference in broadside gain between a dipole and an inverted V is
about 0.5 db.

The pattern from a inverted V with 120 degree included angle (30 degree droop from horizontal) is almost the same as a horizontal dipole at the same height. If the apex of the V is about 1/3 of the droop distance higher than the dipole, the "ground reflection" component is about the same.

For the 10m example here, the dipole is 5m long, roughly. A 30 degree droop is about a meter on the 2.5 meter leg on the dipole. (e.g. sin 30 is 0.5), so putting the dipole a foot higher (30cm) will give you almost the same pattern as a horizontal dipole.

A rotatable
> dipole or 2 el beam would be a simple project.

given the complexity of rotators in general, rigging up two crossed dipoles and a switch might be a better solution.

I've seen various ISP's chunk my usenet for quite a while.
First it was the old dial up I used to use.. Same ole story..
Not many people use it they claim..
The latest was Comcast.. They dumped usenet about a
year ago I think..
The number of ISP's carrying usenet is dwindling fast.
I've been using Google groups since the time that my
dial up shut it down..
Many think I've probably lost my mind, but I've grown to
actually prefer it over the usual usenet readers.
I see the whole thread at once, and don't have to click
each message to read em.. Also.. it's the archive..
So say someone started a thread in 1997 titled
"my tower fell over and crushed my car", and then
someone else came along in 2009 with the same
title, I'll see both of them.
If Google dumps usenet, I'll probably just quit using
it if I can't find any other free web sites. Most of the
others I see have been fairly lousy.. IE: take days
to refresh, etc..
Google has been fairly instant refresh for quite a while
unless something is broke.

Is it advisable to use a combination of Coax and a ladder line to feed a simple horizontal multiband dipole antenna?

In my new QTH it would be very easy for me to get a short run of coax out of my shack window but I would like to use a low loss ladder line for the main run up to the antenna feed point. Is it OK to place a 4:1 balun just outside of the window for the transition?

From: Ocie Lewis <olewis10550@yahoo.com>
Subject: Re: Making Serious Money Online
Date: Wednesday,June 10, 2009, 4:45 PM

~~~~, I Want To Personally Introduce You To An Internet Millionaire!

Hi ~~~,
{Ocie} here with an major
announcement...
http://www.MyPartnersInProfit.com/bootcamp/?id=10286

For 25 people, this will be the most important
e-mail you ever receive. (I hope you're one of them!)

Because my new partner and I are looking for 25 people who are ready
to take part in the greatest Internet marketing joint venture of all
time.

This joint venture is open to anyone. Even if
you have a business already.

Here's the story: http://www.MyPartnersInProfit.com/bootcamp/?id=10286

But here's the catch: In order to make this happen,
We need to be sure that we choose the 25 people most
driven to succeed and responsible people. So if you're
looking for someone to hand you vacations and cars on a
silver platter, then you can stop reading right now.

However, if you have a sincere interest in building
a REAL home business based on something that you
can get passionate about... something you can truly
dedicate yourself to (at least 10 hours per week)
for the next twelve months, then we want to hear from you.

Because to be one of the 25 people accepted, you don't need an
existing online business (but you can). You don't need a technical
background. You don't even need to have any experience. Remember you
are just going to be sending out movies! (we'll work with you on ALL
of these things!)

What you *do* need is a burning desire to succeed
and the ability to be coachable and believe it's possible.

If you want to make an extra $100,000 a year working
part time, so that you or your spouse can stay home
~~~~

with the kids, let's make it happen! If you want to
increase the profits of an existing online business,
so that you make an extra $50,000 - $100,000 per year,
we can help you get there, too!

But please note that because of the huge time
commitment this kind of one-on-one mentoring will
take from me, I can only accept 25 people
at this time and I'm expecting to get literally hundreds
of applications.

So if this sounds like something that might interest
you, we highly recommend that you go to the link below
and watch the short video of my new partner as
he explain everything right away! Then just complete the
application form on the next page.

...We are going to be taking applications first come,
first served as they get accepted.

Don't wait click below or just copy and paste the link into
your browser....

http://www.MyPartnersInProfit.com/bootcamp/?id-10286

To Your Success & A New Partnership,

{From Ocie }

P.S. Keep in mind, we expect these 25 new spots to be
filled extremely fast... Likely in the next few days.
So if you would like to participate, we highly recommend
that you go right now and watch our video, then fill out
the form to get a copy of the movie for yourself, this
will notify us that you would like us to call you and start
working together.

http://www.MyPartnersInProfit.com/bootcamp/?id=10286

you can, but how long of a run will it be from the shack to the antenna??
unless it is a very long distance just go with the coax... the added loss
and complexity of the balun and then the mismatch of the ladder line to the
dipole at the far end is probably going to be more than just going with coax
all the way.

The G5RV antenna uses a combination of coax and ladder line, so this type of antenna is in use by 1000's of Hams.

The 4:1 balun is a bad idea for a multiband antenna, due to the impedances involved at the various operating frequencies. Just transistion from the ladder line to the coax and use a 1:1 choke balun at the antenna input of your tuner. You did not mention an antenna tuner, but you will need one for multiband operation.

In general keep the coax length as short as possible.

Dear Emanuele and Group:

I have been mentioned. The other responders have well indicated the key factors of a Cassegrain antenna. They include having the active devices (transmitting or receiving components) at a convenient location and potentially a somewhat better antenna temperature than with a typical parabolic antenna.

At Ohio State, working with John D. Kraus, we actually used a form of a Cassegrain antenna - the Big Ear. The Big Ear used a (E-W) wide, vertical parabolic surface to concentrate the radiation from a (E-W) tilting flat reflector that was north of the parabolic surface into a feed that was at ground level. The cost effectiveness was outstanding! I could work below the feed in an underground room accessed through a tunnel under the ground screen.

You are commended for initiative in wishing to have a radio telescope. Crafting such an instrument can be an end into itself. However, having an observational goal seems to be desirable if this is more than a construction project. I recommend that you read the ample literature that is available to help you design an observational goal.

Note that you need a large size if you are to achieve resolution, which might not be an objective. I worked on the receiving system for a system at NRAO at Green Bank, W.Va. that used a fixed, high gain antenna to observe (once a day) the strength of one source. The antenna used had a predictable gain and, with calibration, the system was able to provide flux measurements (with an attendant uncertainty, of course). Note that the first real radio telescope by Reber was a parabolic dish - it still exists. (He was a really bright, innovative guy.)

The presence of antennas used to receive satellite broadcasts that use offset feeds should be considered. Such antennas can have desirable antenna temperatures because of the placement of the feed while not having feed-blockage.

Most important is the avoidance of re-inventing the wheel that can be effected by serious study of the literature. That is where I recommend that you start. Kraus' books on antennas and radio-astronomy could be a good place to start. It would be wonderful to be young and have so much learning to look forward to! After over 50 years of studying radio related subjects, I am still excited.

The delay in responding is due to the high noise level in this valuable news-group. Ignore, as I do, the theological debates. Pay close attention to those on this group who are knowledgeable.

Enjoy the greatest pleasure - that of learning. Mac N8TT

I have a triple magnet and hamstick that has survived 70MPH and 50MPH
wind gusts with no problem. We get a lot of wind out here and it has
handled it all for the last 3 years.

I think you are right. Most of the commercial antennas called "G5RV"
have coax supplied with them or instruct you to attach a certain
length coax.

One of Reg Edwards programs, Dipole3 models a twin lead-coax miltiband
antenna. It also has a G5RV feature.

The G5RV antenna uses a combination of coax and ladder line, so this
type of antenna is in use by 1000's of Hams.

The 4:1 balun is a bad idea for a multiband antenna, due to the
impedances involved at the various operating frequencies. Just
transistion from the ladder line to the coax and use a 1:1 choke balun
at the antenna input of your tuner. You did not mention an antenna
tuner, but you will need one for multiband operation.

In general keep the coax length as short as possible.

Gary N4AST

Another thing to consider is that the length of the 450/300 ohm twinlead
feedline is an important factor when considering the operational bandwidth
of said "dipole" antenna (it's only a dipole when operated at its resonant
length).

The twinlead is utilized as part of the radiating system when operated on
certain bands. This unusual impedance is why the tuner is needed. Shortening
the twinlead and using more coax limits this antenna's ability to operate
over wide frequency ranges. My Van Gordan All Bander's twinlead enters my
shack and then connects to a balun, which is then fed by coax that is
connected to my MFJ-989C tuner. I can often tune down into the 160 meter
band using this setup, though I wish my twinlead feedline length was a bit
longer for even greater tuning flexibility.

By the way, my All Bander also works great on six meters.

I use a combination of window line and coax for my 80m antenna. I
don't have enough space for a full size dipole, so I had to shorten it
somewhat. From memory, about 6m of window line makes up for about 3m
of missing wire on each dipole leg. Easier to do than loading coils,
that's why. EZNEC claims that losses are negligible, don't know if
that's really so or a transmission line model is inappropriate here.

Totally by accident, the antenna also ended up with a resonance in the
30m band.

In Varney's original r.s.g.b. article in July 1958 he showed it both ways, 100% open wire feeder to a tuner, or 34' of open wire feeder to any length of 72 ohm coax or twin lead to a tuner or the transmitter.

I agree with Gary N4AST: the direct answer to your question is:

* Use the shortest length of good quality coax you can get away with.
* Use a good quality 1:1 current (choke) balun at the ladderline/coax
junction.
* If you find the tuner can't reach a match on some bands, only then
consider a 4:1 balun; even so choose a 4:1 **current** balun.

On the topic of G5RVs, some (unscrupulous) antenna suppliers provide a
nice long length of RG58 as part of the package to "tame" the VSWRs.
Take a look at some of the losses that introduces:
http://www.karinya.net/g3txq/g5rv/

I have to chuckle when you bring this up in a discussion of that true chimera, the G5RV. I've heard so many antennas called G5RV's that the term means nothing any more - kinda of like scotch tape.

So yeah, I guess we should call it a doublet. Of course, all doublets are dipoles at some point, and all dipoles are doublets.....

Well that is great, glad it hasn't been a problem, Erich. But I'd feel pretty stupid to try that sort of mount again, unless someone wants to front the 275 dollars I just paid to put a new window on. Then I might experiment.

Could be a weak or otherwise bad magnet, maybe just bad luck-who knows? But the antenna will now be mounted just like my Bugcatcher, which means it will only come off if there is enough force to pull the back door off, or otherwise destroy the antenna in situ.

Thanks for all your responses and ideas.

Yes, I do have an antenna tuner. The maximum length of the antenna I can hope for can only be about 65ft because of the placement of trees in my back yard and access to my shack. At this time I will be happy if I can tune to some bands up to 40M. I did not want to drill any additional holes for outside access if I can help it amd make use of the existing one. I also wanted the option of total disconnect from the outside. My equipment has been fried by lightning in my previous QTH.

I figure it would be about a 60 ft run to the feed point. I am aware that certain feed line lengths are to be avoided to minimize transmission line radiation and tuning problems. In addition to low loss I thought ladder line would be much lighter than coax. I don't have any way to support my antenna at the center so I am trying to keep it as light as possible. Not sure of the wind loads though but I will have a modest workable antenna up soon.

You all have been very helpful in sharing your thoughts.

Yep, I'm still documenting. Perhaps, there are alternatives to a Cas
antenna (Yes, I admit, because of exams I haven't crafted it yet, but
for me this is a very long term project), like a little array of offset
parabolic antennas.

This is interesting!
How much time did it take to make a complete radio stellar map?

> Note that the first real radio
> telescope by Reber was a parabolic dish - it still exists. (He was a really

Reber's parabolic dish is giant :) My site is situated in countryside,
and it could be able to host dishes of max 3 meters of diameter: the
data would be transmitted over the internet to my home (near Naples, ITA).

Thanks again for reporting your experiences and the advices!

I haven't read Kraus book about radio astronomy: my sources are Collin and some italian books by Flavio Falcinelli. But now I'll surely look for this book too!

Well, that wasn't the point that I was trying to make.

I was saying that the length of the twinlead is very important and that it shouldn't be shortened (commercial versions) any more than necessary, lest one lose some of the utility of this type of antenna. I know that folks are eager to transition to coax, but that isn't the way that leads to the best working sample of this antenna.

Dear Emanuele:

Do well on your exams. It is that time of the year here as well.

It occurred to me that I had quite forgotten that two dishes exist associated with Reber. One is huge and the other is the 9.5 meter dish he built himself. Both are at NRAO. Reber was a true scientist and a great friend of my mentor, Kraus. Here is a story about him: http://www.nrao.edu/whatisra/hist_reber.shtml

The maps he published just before the war, were studied by Dutch astronomers who were sequestered during the war. After the war, the Dutch moved the field forward. Reber's interests were many. You will note papers on beans, for which he performed truly original work much of it while we were both at NRAO. After dinner, when one learned not to leave the meat platter too close to him, he would go off to inspect his research garden. He was a collector - not quite the right word, but close - of early radios. I have seen him get them working, construct a box that would just hold the radio, and then store the boxed radio for a future museum. In his testing of old (pre war) radios he discovered that one company had discovered stagger tuning. His note on that subject caused a lot of noise.

His observation - known to everyone in the radio field - that the ionosphere was most thin near VK7, resulted in his measuring radiation from space at low frequencies well before satellites. His genius of seeing in common knowledge new possibilities is his hallmark and one that I wish for all who would push knowledge forward. He constructed all of his own measuring instruments, which were strikingly beautiful. I spoke to radio amateurs in VK7 while he was still alive and they told of how beloved he was by the people of that island.

By the way, my first name is James, not John. I use "Mac" as it seems more suited to this newsgroup than "Professor."

It is just possible that the sort of offset-feed antenna for receiving broadcast signals is not common in Italy. If that is the case, a search will uncover surplus dishes in North America. They tend to be in the one meter size, which might be too small unless used in an array. I am told that surplus, conventional dishes show up from time-to-time as agencies/people move or up-grade. I like the idea of operating remotely.

Study, learn, plan, do, observe and you will learn even more. Consider getting an amateur radio license.

Warm regards, James / Mac N8TT

Hi Emanuele

The probability of your realizing any success with parabolas less then 10 feet diameter using cassegrain systems is extremely low at L-band. I realize that you are able to decide for yourself, which antenna system is best for your project. I do want to alert you to the fact that the beam from the "source radiator", behind the dish, needs to be shaped to be concentrated on the reflector at the focus. There is not enough room in a 3 meter dish to provide access to a primary feed with the narrow beam required for realizing the benefits of a cassegrain feed.

I have has some succes with a 1 meter off center fed dish at L-band (1.691 GHz) for redceiving signals from a geosynchronouis satellite. The feed I designed for that dish might be of some use to you.

Jerry KD6JDJ

You might also look at the design for the Allen Telescope Array, which
is a Gregorian feed, and is offset.

All of these are useful to have minimum noise contribution from the
surrounding earth.. if the feed over-illuminates the secondary
reflector, you are still looking at cold sky, unlike with a prime focus
sort of feed, where overillumination looks at the dirt behind the reflector.

There's a set of articles in IEEE Antennas and Propagation Magazine (not
the transactions) a few years back that has all the equations and design
rules for all of the various reflector configurations.

As for reflector sources.. 1.5m parabolic reflectors intended for offset
feet are readily available in Europe. They're used by British

Expatriates in places like the Canary Islands to get BskyB broadcasts (since they're well out of the satellite footprint, they need more gain than the usual 50cm sort of dish on the side of your house).

A couple years ago, I remember googling for reflectors of this size for a project and ran across this kind of thing. The reflectors were real cheap (10-15 pounds), but shipping to the US would cost many times that. They seem NOT to be readily available surplus here in the US.. VSAT stations in Alaska might be the only application.

If it were me and I were using a tuner, I'd just run ladder
line the whole way. I've noticed that even if you pass
the line across a metal window frame, there is usually
no noticeable change to speak of. If you have to do that,
it's best to keep the line at right angles to the frame to
keep it as balanced as possible.
You could easily chunk the line outside during storms,
or you could rig up a way to disconnect by using
banana plugs, etc.. That way you can disconnect but
not have to fiddle with unplugging from the rig.
I would prefer to have those outside, so when
disconnected the line is totally out of the house.
It's probably quite well known on this group that
I don't like mixing feed line types in a case like this. :/

Running ladder line the whole way is the least lossy
vs mixing ladder line with coax, choke, etc..
Using G5RV type feeding schemes will work, but they
can take a decent hunk of your RF and turn it to heat
in many cases.
Even with a 80/1 mismatch, ladder line has low loss.

If the length of coax is short, the loss will be fairly low.
But.. many add a choke, etc, and I think the choke
is where a good portion of the loss is on these type
of feed systems. Some of these might use fairly long
coax lines, and the loss could add up vs ladder line.
BTW... Tune the tuner using the least inductance
needed to get a usable match whichever way you go.

Oh well, having opened a spreadsheet with VBA macros, and clicked away an error box a hundred time, I got to the point where the macros were visible and I could see that the OO implementation would not tell me the number of rows in a variant array of variants passed as argument #1.

I will look again in a few years.

Looks good, but it sure doesn't work like Excel 2000, not yet anyway.

Owen

Often, but not always:

* Depending on the impedances, frequencies and lengths involved, the loss in a coax section can be lower than in the equivalent length of ladderline.
* Although there may be losses in a 1:1 current balun at the ladderline/coax transition, don't forget that there will also be losses in the tuner balun if ladderline is used all the way; if the ubiquitous 4:1 tuner internal voltage balun is used, those losses could be significant.

Maybe, instead of 'ubiquitous', read 'inappropriate' (at least on
certain occasions). I'm sure that, if you can't resist the urge to use
coax, a current balun / longitudinal choke (often wound from the coax)
could have much less loss.

A hundred years ago I had the older one -- I forget now which of the "T"
or "Q". The older one had large black plastic, old style 2-lb
coffee-can-sized (for the rest of the world: approx. 20cm Dia. x 10cm H),
coil and capacitor traps.

I obtained mine used and, in reality, it was a 12AVT-or-Q. I don't know
if it was sold that-a-way: a 10-15-20M model, or if it was "re-engineered"
before I got it.

Anyway, I believe the difference was in the traps -- the newer models
being of the "aluminium sleeve" style.

AS expected, local channels 8, 10 and 12 moved their digital
broadcasts back to their VHF assignments last night. They
had been temporarily broadcasting digital in the UHF band.
I was expecting to have problems with my dual bowtie antenna.
But this morning I rescaned the channels (and verified that
the move had taken place). Then checked reception on the
affected channels. It was great. No problems. All that
worrying for nothing. Thanks for listening.

One situation that cropped up in my area (Cincinnati) is that channel 9,
which was broadcasting digital on channel 10 VHF, had to wait until just
before the conversion to raise their DTV antenna from 100 ft down to the
top of their tower. We're also using a dual bowtie, and their change
made a difference.

Maybe not THE factor in your case, but glad things worked out for you.

30m of Wireman 551 with a load of 5+j0 has VSWR=80 at the load end, VSWR=28 at the source end, and the transmission loss is 4.6dB... 65% of the input power is converted to heat.

Speaks to your meaning of "low loss".

Mythical properties are ascribed to ladder line, some of attributable to ARRL publications.

Owen

I should have mentioned:

what especially interested me about this is how relatively unimportant
antenna height has seemed to be in my microwave work.

Until this past year (when rotator cuff surgery took me out), I had been
doing quite a bit of microwave work as a rover (903 MHz - 10 GHz). I was
often impressed by how far over the horizon it would work with an antenna
only about 5 ft off the ground and about 1 W of power.

Granted we were working with MUCH lower signal quality requirements than
the TV stations, but I still am surprised by how poor our reception is of
DTV channel 12 (and earlier, ch9), which is transmitting MANY kW from a
multihundred-ft tower only about 16 km away.

Engineers may argue otherwise, but it still seems to have a certain
element of black magic to me :-)

Or, I think more properly, to statements in ARRL publications taken with
a different set of underlying assumptions..

For instance, ladder line between a tube amp output tank and a doublet
is probably "reasonably" low loss in most common practical applications..

And in an inappropriate application (reactive load with weird Z to 50
ohm transmitter) it's probably lower loss than RG-58.

Maybe it's that subjective term "low loss"???

Half a dB per foot is low loss at 32 GHz, but you'd be hard pressed to
find a commercially available transmission line with that kind of loss
at 7 MHz. (maybe that funky 1000 ohm Z delay line stuff?)

Ham applications in any case are kind of an odd thing, efficiency-wise,
since the limit is on RF power at the transmitter output connector.
Pretty much every other user of RF power amplifiers sets the system
measurement plane somewhere else.. in space (EIRP or ERP) or at the
power source (power budgets). For instance, you can trade increased
power consumption against lower feedline loss.

I dare say you weren't transmitting digital data at 20 Mbps in a 6MHz
wide channel as a rover.

CW or SSB with a bandwidth of a few hundred Hz or maybe a couple kHz at
a SNR of 0dB vs 6MHz BW and a SNR of 20dB

30-40 dB of increased noise bandwidth
20dB more signal power relative to that noise for decoding

There's your 100kW right there (100kW = 50dB over 1W)

And, transmit end of the link has lower gain than you probably use as a microwave rover, because it's omni (in the horizontal plane, at least). A 1-2 degree beamwidth works out to about 30dB in gain

This kind of thing is why working the world with 10W on PSK31 is pretty straightforward, compared to SSB.

Thanks Bert,
But I have already been there and done that, and I do appreciate your time
in replying to my query. I have copies of the online manuals of both of the
antennae that you refer to.

So the question still remains, what is an AV-18AVQ???

Someone out there in Ham Radio Land must have a copy of a manual for the
AV-18AVQ in PDF format and would like to share it.

Cheers & 73
John

Well, it's the 'big day' and while we have an excellent antenna at
work, I didn't think the little 'SquareShooter' would be adequate for
VHF-hi (channels 7-13) DTV. I brought home the spectrum analyzer to
check out the signal before I tried a re-scan. So far 2 of the 4 VHF-
hi have completed the change over. KABC-7 and KCAL-9 are in their new
homes. The spectrum analyzer showed better than 20dB carrier to noise
which should be OK. I then connected to the computer tuner and it
works very well. I must say I am totally surprised about that as the
analog stations 7-13 were SO weak as to not even SEE a locked umage
from analog. As it is, it appears to be as good as the UHF DTV. If Fox
11 and KCOP-13 are as good as 7 and 9 I won't need to change a thing.

> with a different set of underlying assumptions..

The ARRL has long published characteristics of "Generic ladder line"
being #18 conductors spaced 1". They publish loss figures better than
theoretical loss for the same size copper conductors in a vacuum (eg at
10MHz, about 0.27dB/100m vs 0.47dB/100m).

The second factor is, I think, the notion that since one-way loss is
relatively low on open wire lines, that it is safe to consider it
always insignificant (irrespective of VSWR), then exagerate the point
by talking about it being essentially lossless at extreme VSWR.

I think that the best characterisation we have of ladder line is that of
Wes, N7WS. Similar measurements at lower frequencies might well reveal
whether the stranded copper clad steel versions have inadequate cladding
depth for copper-like performance at low HF.

>
> For instance, ladder line between a tube amp output tank and a doublet
> is probably "reasonably" low loss in most common practical
> applications..

Perhaps a better concept is "acceptable loss" where acceptable is
influence by the application. The compromises accepted for multiband
operation might well include 3dB of line loss on the lowest band.

...

> trade increased power consumption against lower feedline loss.

Actually, interesting you mention that.

I recently had cause to probe the meaning of the term "transmitter" in
our (VK) regulatory framework. Whilst we are limited in transmitter power

output, the meaning of transmitter is relevant.

From our legislation:

===quote

8 Definitions of radio emission and transmitter

(1) For the purposes of this Act, a radio emission is any
emission of electromagnetic energy of frequencies less than 420 terahertz
without continuous artificial guide, whether or not any person intended
the emission to occur.

(2) For the purposes of this Act, a transmitter is:

(a) anything designed or intended for radio
emission; or

(b) any other thing, irrespective of its use or
function or the purpose of its design, that is capable of radio emission.

=== end quote

It could be argued that an "emission" exists beyond the antenna ("without
continuous artificial guide"), and that everything up to an including the
antenna could be captured as part of a "transmitter" as defined.

Though there is a well understood ordinary meaning to the word
"transmitter", the drafters of the legislation have provided a definition
that should override any ordinary meaning in the context of that law.

Perhaps we (VK) are entitled to apply our limit to radiated power!

It's a mistake to lump all ladder and window line together as "ladder line" and draw conclusions about its loss characteristics. There's a vast difference between punched polyethylene window line and real 600 ohm ladder line made with large diameter conductors and low loss spacers. Even more so when the line is wet.

Yes Roy.

I was talking about the commercial "ladder line", and used the example of Wireman 551 which is of the punched polyethylene window line type you mention.

The other comparison I made was the ARRL "Generic ladder line" whatever that means with ideal copper conductors of same dimensions in a vacuum. I cannot see how adding insulation can possibly halve its dB loss, can you?

==========

I got KABC but, so far, no KCAL. I'm in San Diego, so my situation will be
variable, depending on the ducting. I think I've lost KCBS, since they
moved to KCAL's old channel, 43, which has a local LPTV station sitting on
it. I still have some more antenna tricks to try. KCAL on 43 was always
very "iffy."

I've also lost KCET; There's a Mexican station (full power) on 28. KOCE
generally good.

My optimism was premature. KABC is better than I expected and KCAL was
marginal. KTTV-11 Fox is way down in the mud and KCOP-13 is worse than
11, neither of which is usable at all. Keep in mind this is that
little SquareShooter (without the preamp) which is good for UHF isn't
going to make it for VHF hi. Oh well, some more cable along with a UHF/
VHF splitter (combiner) and that big Winegard in the garage will

hopefully cure it.

At 12:30am 6-13-09 KWHY-22 analog was still on the air but all that's left are a few low power analogs - as they told us.

Yup. 1 W to a 60-cm (2-ft) dish at 10 GHz yields about 2 kW ERP with a 3.5 degree beamwidth.

> This kind of thing is why working the world with 10W on PSK31 is pretty
> straightforward, compared to SSB.

I know how to do the system and path loss calculations. Yet I'm still impressed when I can work another rover at 300+ km, sometimes with S9 signals and then go home and see the choppy signals I sometimes get between ch.12 at 300 m HAAT and my antenna at more than 10 m HAAT.

Amateur microwave work is pretty cool stuff :-)

BTW, using roughly 2-m dishes and only 100 mW, amateurs have transmitted 802.11b (WiFi) and higher-rate signals around 300 km several times. This allows digital video and audio. I think the current record is 389 km.

How interesting, so in both VK and UK (mixing abbreviations).. the "reference plane" for the measurement is potentially "after" the transmission line. The 5kW Active Antenna Tuner lives!

Here in the US, I'm sure the rule is interpreted the way it is because of the heritage of "1kW DC power to the final stage" rule, which in turn came from pre-ham radio rules for marine transmitters using sparkgaps, etc... It was simple change from measuring plate current/ voltage to hooking a power meter at the output connector. I wonder if anyone ever measured RF power on a non-50 ohm transmitter in an enforcement action?

My father and grandfather both had stories, apocryphal perhaps, about clever hams having very large "exciters" that fed through a relatively low power "final stage"... using the final tube as a coupling capacitor, perhaps, with unity gain.

By this little snippet of what was intended as an aside may, in fact,
be your solution for VHF. Given your predicament of "code" (arbitrary
or otherwise), you can put the cable to work.

The solution is called a "Franklin Antenna." It would be disguised as
an antenna cable (or telephone cable, or power line, or other
innocuous wire) that trails up (to something innocuous), but never
connects (who is going to look? and if they did, it could always be a
dummy connection).

A Franklin antenna is a stacked, gain antenna that is very colinear
(hence the cable motif). These are most often described on the Web
for home wi-fi or bluetooth applications, but with scaling you can
bring them back down into the TV VHF band. A quick search gives:
http://www.para.org.ph/membersarticles/DU1ANV/Development%20of%20Collinear%20Antennas_Matching%20and%20Feeding%20Techniques%20-%2021.pdf
which on page 11 gives a pictorial representation (I can't say I vouch
for the entire paper, but it is representative of the topic).

I might have been a bit carried away with the degree of mismatch
and loss, but I still think running the ladder/window line the whole
way to the tuner will still be the best in most cases for "all band"
use.
If the major portion of the feed line will still be ladder line, even
with
the coax lead in, he will still deal with the same line losses for the
majority of the run with such a severe mismatch.
It won't be that bad most of the time.
With the coax and choke addition, even more loss is added to the
system. And if he saw an 80:1 mismatch, just 15 feet of RG-8
should cost you half your power at 14 mhz. That's more loss than 15
extra feet of the ladder line which at 80:1, should be about 1 db loss
or so.
I just find the addition of the coax and choke as totally unnecessary
unless there is no way at all to feed the ladder/window line through
to the shack.
Sure, there are losses with the balun used in most tuners, but I
consider that a price to pay for a multi band antenna.
Myself, I don't use many all band antennas..
Most of my dipoles are single band, and coax fed. :/
Here is one online calculator which seems to match your
numbers fairly close if set for 14 mhz. They include the
551 line as one of the choices.
I notice "generic" 450 line has less loss.. I don't know

what the difference is between generic and 551..
Maybe 551 has more plastic, and less open window..
I notice generic 600 ohm ladder line will show about 2.2 db
loss with an 80:1 mismatch. I'll agree.. Maybe not low loss,
but it's quite usable considering an ugly 80:1 mismatch.

Hi Emanuele

I submit that, if you intend to actually build an antenna for L-Band and
are restricting its diameter to 3 meters, you need not consider a cassegrain
feed. The reflector at the focus is too small to allow the primary feed to
illuminate it with a high percentage of the available source at the rear of
the dish.

For one example, let the cassegrain reflector be 1/2 meter diameter and be
spaced 1meter from the apex of the dish. Wouldnt that suggest that the
primary beam, from behind the dish will have a beamwidth of about 30 degrees
(at -3dB)??
If the cassegrain reflector is made bigger, that blocks more of the
parabolic dish apperature. If the cassegrain reflector is made smaller,
that increases the need for a high gain primary feed.

It is my contention that, if you want to research Cassegrain antennas,
that is a worthy project. If you want to build a functing L-Band telescope
with 3 meter dishes, dont include cassegrain feeds in the project.

The only problem is that a Franklin antenna is usually vertically
polarized. TV is horizontal.... well some station have a vertically
polarized component, but it's mostly horizontal.
<http://www.tvtechnology.com/article/68820>
The Franklin antenna is not very wide band, covering perhaps a few UHF
channels, but certainly not the entire UHF TV band.

Topic drift: Franklin or AMOS antennas for Wi-Fi. NEC2 deck is under
the "main" page and is easily scaled for your favorite TV channel.
<http://802.11junk.com/jeffl/antennas/AMOS-7/index.html>
<http://802.11junk.com/jeffl/antennas/AMOS-5/index.html>

I don't have photos of the "disguise" TV antenna I installed on top of
a 175ft redwood tree. It was vertically polarized, crammed into a PVC
pipe, and filled with urethane foam (fence post compound). 20dB gain
wide band GaAsFET amp at the base. It was painted brown, to match the
tree trunk.

Performance was a disaster. There wasn't enough gain so most stations
were noisy. With an omnidirectinal pattern, it did a superior job of
converting reflections from the surrounding mountains, into obnoxious
and irritating ghosts. 4 tries, and no luck.

The plan was to install a pully near the top of the tree, and use a rope to raise and lower verious experiments. Unfortunately, I used a rope that did not do well in the sun. After about a year of trial and error, the rope crumbled. The pully is still in the tree and can probably be used again.

As for other disguise antennas, I've done some tinkering characterizing various road signs for operation as antennas. The aluminum sign is a tolerable radiator, but the galvanized steel support is a problem. I've also seen all manner of urethane sculptures, designed to resemble a tree, cactus, building materials, lamps, boulders, etc, each with an antenna behind or inside. Also fiberglass panels for hiding antennas in the sidewalk.

I've also crammed wi-fi repeaters inside a plastic owl. I've disguised a wi-fi antenna by making it look like a giant bird nest. If the neighbors asked, I told the owner to tell them it was a Roc nest. <http://en.wikipedia.org/wiki/Roc_(mythology)>
For HF, I've loaded into the rain gutters, installed chicken wire under the carpeting for a ground, and strung wires between telephone poles.

Hello Peter,

The point where the fields merge to the EM wave depends on various
things.

There are three field zones used within the antenna community:

1. The far field zone (Fraunhofer region), where there is a true
spherical wave behavior, and the radiation pattern of the antenna is
independent of the distance to the antenna. The antenna can be treated
as a true point source emitting EM waves. The far field zone is mostly
taken r > 2*b^2/lambda, where b is the largest size of the antenna.
This formula is very conservative. Depending on the current or
aperture distribution, the far field can start from r > 0.5*b^2/
lambda. E- and H- field is proportional with 1/r (r=distance).

2. The transition field zone (Fresnel region), where the fields have a
reasonable wave character, but are not spherical. The radiation
pattern of the antenna depends on the measuring distance. This one is
tricky. An antenna with a null in the far field pattern may show
significant radiation (in same direction) in the transition field. So

within the transition field, you cannot for sure assess field strength levels based on the far field radiation pattern. Also the main lobe in the far field pattern may not be the main lobe in the radiation pattern measured at distance far below the far field distance. You can compare that with coherent light passing through a round aperture, you get an onion shaped ring pattern on the wall (airy disk). You can even get a black hole in the center at certain distance. So here field is not proportional with 1/r.

3. The reactive field zone. This is the region where you can calculate the fields using electrostatics and induction. In many cases, fields are 90 degrees out of (time) phase. r<0.16*lambda is used frequently. Of course, there is no hard distance where the reactive field zone stops and the transition field starts. The decay of the H and E field are different depending on the antenna and the orientation of the antenna.

For small loop antennas, r > diameter AND r<0.16*lambda, H field decay is proportional with 1/r^3.

Another example is a HW dipole. It does not radiate on the axis of the dipole. But when you are at (for example) 0.5*lambda from the ends (but on the axis), you will sure measure an E-field (because of the reactive fields that decay with r^3 to r^2).

Another example is the field between a wide parallel strip
transmission line that is well terminated (strips face each other)☺.
Both E and H are virtually homogenous between the strips, are in time
phase and are spatially 90 degrees out of phase. So there is a plane
EM wave traveling between the strips (no reactive issues).

The situation becomes more complicated when interaction with other materials is present also (for example reflection on metal sheet). You can have points where you have only E, but no H, and vice versa. This is comparable with reflection in a transmission line.

Sorry for the long text, but I hope it is useful.

Best regards,

Wim
PA3DJS
www.tetech.nl
please remove the obvious three letters in the PM

Thanks for the reply Wim

That is a great explanation. I assume from the explanation that the EM wave will due to interaction with path feature i.e. building, ground etc. have more of less of the various zone components. I'm thinking for example as the EM wave passes a hill it may have some of the Fresnel region characteristics that would manifest as say the so called knife edge effect.

Cheers

You must be drunk because I know you cannot possibly be
that ignorant. You are saying that since all calico cats
are female, then all females must be calico cats. Good Grief!

FYI, RF photons are indeed emitted by decelerating electrons
which are being decelerated by the RF source field supplied
to the antenna conductor. It has absolutely nothing to do with
Bremsstrahlung radiation which is completely outside the
context of these postings. Congratulations on another feeble
attempt at a diversionary obfuscation. You seem to be trying
for the record for such nonsense.

I hung the spectrum analyzer on the Winegard all channel antenna in
the rafters of the garage. The VHF channels are strong and free of
response 'bumps' (meaning no serious multipath) and the UHF may be
better than the squareshooter on the roof. Tomorrow I shoot a hole in
the stucco wall to get the new RG-6 coax (crazy guy at Torrance
Electronics sold me 100 ft for $9) pulled in to the splitter to feed
the computers and STB. It looks like it will be good.

Shannon's equations provide most of the answers:
http://www.st-andrews.ac.uk/~www_pa/Scots_Guide/iandm/part8/page1.html

Some of that is hard to follow, but the net effect is that you need a
certain (minimum) amount of power to send a complex signal in a confined
bandwidth. With ATSC, they put about 20 Mbps into a 6 MHz channel. To get
a decent SNR (16 dB or better), they need MANY KW.

I did a little mickey-wave engineering, myself. Point-to-point is easier
than broadcast!

It was identifying the reflection of radio signals from a flying
aircraft that led to the development and use of radar.
Radar was major factor in the successful defence of Britain (Britain
1940) against German bombing (The Blitz) early in WWII (1939-1945).
Although it was initially very crude, (It was called Radio-location or
RDF, Radio Direction Finding) at the time.
Unfortunately the first war time US use of radar was misinterpreted
when the Japanese attacked Pearl Harbour in Dec 1941!

To me, it's a partial explanation, but not most of it. Microwavers often resort to quasi-scientific explanations like "troposcattering", as do VHF-ers. And sometimes the explanations get even fuzzier, like "enhancement". They (and ducting) are somewhat predictable, but as a rover the operating mantra was always just 'Let's try it".

Shannon's equations don't actually tell you much that's useful, as a Ham. And even in a lot of commercial situations, it can be hard to be sure what assumptions to make about noise and signal strengths, for example.

>
> Some of that is hard to follow, but the net effect is that you need a

>
> "Sal"

As an amateur rover, I generally found point-to-point to be more difficult, because of simple real-world Ham issues that don't have a lot

to do with heavy theory. At 10 GHz, a 60-cm dish has a beamwidth of about 3.5 degrees. The rovers can cope with that with some care, but it seems many fixed stations are using rotators that don't provide that kind of resolution. So it could be hard lining up. In contrast, over-the-horizon signals smear out a lot horizontally. I once estimated another rover who was 180 km away as having about a 45-degree signal width, and found 20+ degrees to be common.

Besides that, 10 GHz, and sometimes 5.7 GHz, will occasionally do downright freaky/cool things. Rainscatter is one fun example. And I once worked a station (S9, SSB) over a 50+ km path with a 90-degree bend in it, because the "line-of-sight" path was heavily obstructed by trees etc. We told each other we were bouncing off downtown Cincinnati, which was not visible over the horizon.

I guess I'd like to end this sales pitch with the note that the Ham microwave bands can be great fun. The advantages, and Ham capabilities, of playing around with "real radio" and the small antennas that involves can be substantial.

50 MHz and up ... Everything else is DC.

>Ham.

This would presume that the Ham is rather indifferent or incapable.
Shannon's work is exceedingly useful, and at the core, quite simple to
perceive which further illuminates those mediocre qualities of your
Ham. It is unfortunate that the link above offers no graphs by which
Shannon's points would become startling apparent.

For instance:
http://www.aero.org/publications/crosslink/winter2002/images/04_04.gif
shows how signal to noise ratio has a vast effect over bit error in
digital transmission. In the face of equal powers (noise and bit
level), you would run the odds of 1 bit in 10 being mistaken (pretty
good odds, actually). If you were to raise the power in the bit by
10dB, that would fall to 1 bit in a million being mistaken.

In the same graph, Shannon reveals how, if you code your bits (I will
leave it to the student to discover the meaning of that), you could
achieve the same 1:1000000 advantage with the addition of less than 1
dB of power boost.

Until fairly recently, hams didn't do much coding, for a variety of reasons. Computational horsepower is probably a big reason. Coding's easy, decoding not so easy, at least in a "parts readily available from Radio Shack" sort of sense. Obviously, today, one could do all sorts of coding on a laptop PC, particularly at low bit rates, but you'd still need to have an unusual convergence of someone who knows how to implement the coding algorithms who's also interested in amateur microwave operating. It's not anything like a turnkey thing, or even a "go get gnuradio" thing. Where you see coding in common ham use, it's buried in an application (PSK31, JT65, and the like)

The other problem is the frequency control issue. If you want low rates and ragged edge of Shannon, you need good frequency stability and control (and to a lesser extent, good phase noise). Until recently (with GPS disciplined oscillators and surplus Rb sources) this was a real challenge. As Rich commented with respect to antenna pointing, you also have to be right on for frequency, and that's hard, especially in a field situation. Tuning to 10Hz accuracy at 10GHz implies 1E-9 frequency accuracy, which is challenging. To a certain extent, processing power in a PC helps (get close, do parallel demodulation, find the signal), but just like for coding, it requires finding a person (or small group) who can deal with building low phase noise stable oscillators AND with developing software that is somewhat complex, compared to the usual "whack it out in a weekend of coding" stuff.

I suspect there ARE hams experimenting with this, but it's a long way from critical mass wide acceptance. You need something that you can write an article in QST, and offer <$100 widgets to make that happen. There's not much cheap surplus gear either, since commercial equipment these days tends to be more specialized and isn't as amenable to hackery.

There are also proprietary rights issues with some coding techniques (e.g. Turbo) but I suspect that legal issues aren't what's holding hams back. For things like LDPC, there are published software

implementations that are free to use. I haven't looked but I imagine that various convolutional codes and decoders are also publicly available, along with Viterbi soft-decision decoders.

This neither negates the specific issues of signal to noise in their relationship, a matter that is quite in the power of the Ham to control to some extent; nor does it invalidate the simplicity of that relationship revealed through one graphic that serves to reduce the obscurity of a lot of math.

As for the variety of reasons, computation power would seem to be in abundance (the first mythical Cray is a door stop today). That as an excuse is a croak.
>It's not anything like a turnkey thing,
Like I said, an indifferent or incapable individual in the guise of "Ham." I am amazed how that Lid is raised on a pedestal.

So, let me get this straight, because it is available (a seeming contradiction from the tenor of your response), it is not accessible? Or it is not useful? Or it is not understood? Or Shannon has been rendered obsolete?

Your objections are answered with your own solutions and yet the sense of what you say is shove Shannon out the window and whine about the noise.

Well, I do admit that I went overboard there! Probably shouldn't speak too quickly about moonbounce, meteor scatter, etc. I do think, however, that for many Hams (me, at least :-)) the applicable word is "indifferent" rather than "incapable".

If you can genuinely find useful application to what microwave rovers do -- or most microwave operators, for that matter -- that would be a special contribution. I expect that would be even less likely for most HF and VHF operations.

I'd characterize Shannon's work as more of academic interest (for most Ham radio) than practical interest. In most of what most Hams do, there are just too many other issues to deal with.

Please note the use of the word "most". I'm sure there are exceptions, but I expect they're a small part of hamdom (as is microwaving, sigh).

I think you've hit the nail on the head..

If you're communicating with deep space probes, you've probably
already eked out the last tenth of dB everywhere else in the system,
so you can worry about coding and how close you are to the Shannon
limit.

If you're a ham, especially microwave rovering, then getting the last
couple dB is the least of your problems. It's easier for the ham to
get 3dB by some other means than, say, implementing coding.

Where some kind soul has made using coding easy, it's used (e.g.
JT65).

Don't even need the switch.. Just feed the crossed dipoles
with a single coax line and off to the races. :)

Truly. I just hung 40m from 80m wire with some spreaders. If I had more
wire I would add a couple more at 80m just for bandwidth.

I doubt that 6 and 10 meter cause any interaction with a common feed. At
that size a rotatable dipole is easily made with mobile whips. A rotatable
dipole takes advantage of the deep nulls.

A dipole with 120 degrees included angle is just a droopy dipole. An
inverted V with 90 degrees included angle or less has a combination of
vertical and horizontal components to its radiation and is more
omnidirectional. More so with a metal supporting mast.

You might want to take a look at W1GHZ's online book
http://www.w1ghz.org/antbook/conf/Multiple_reflector_antennas.pdf

He gives a procedure, and refers to a variety of sources, among them,
the ones I was thinking of:
The articles I was thinking of were by Christophe Granet at CSIRO in
Australia, and published in Tom Milligan's "Antenna Designer's Notebook"
column in the A&P Magazine

April 1998, "Designing Axially Symmetric Cassegrain or Gregorian
Dual-Reflector Antennas from Combinations of Prescribed Geometric
Parameters"

June 98, Minimum blockage
Dec 99, Displaced axis dual reflector antenans (4 types)
Dec 2001, Dragonian Dual-Reflector
June2002, Offset Cassegrain or Gregorian
Dec 2003, Designing ..offset.. Part 2, Feed-horn Blockage Conditions.

There's some FORTRAN available too, from Tom Milligan.

I have a set of rabbit ears that was given to me several years ago for the TV in the bedroom. The antenna cost about $15 in the 2002 catalog (Radio Shack quit publishing a catalog soon thereafter).

I use a digital converter made under the RCA name and after the scan virtually all of the pictures came out far better than the old analog reception. However, almost all say "cannot get good reception rescan". The sound tiles in and out. The bedroom is on the second floor. I looked at amplified indoor antennas at Target and they sell for $20 to $50. The non-amplified is $18 (only one they have).

Do most go to an amplified antenna or use an outside antenna? I just took down my old big outside antenna 3 years ago as we have Comcast cable in 3 rooms. Comcast cost $$$ for each set up and add more wires to the house. I also assume the signal gets weaker the more I add.

I switched to digital about 3 years ago. All over-the-air, no cable or
satellite. The little bit of TVI had been seeing went away entirely when
I switched.

On the other hand, it means I no longer live in a channel 2 area; maybe I'll finally try 6 meters.

The program that works like Excel 2000 the best will always be... Excel 2000.

The vast majority of Excel spreadsheets are just "data" without any macros, and import into OO without difficulty. As soon as you start adding automation to those Excel spreadsheets, though, you're venturing into waters where OO might still be a good choice, but you definitely have to start planning on spending time fixing things. This is true with any other spread that claims to be able to import Excel files as well... although certainly some will tend to be better or worse than OO in specific instances.

Rabbit ears aren't the best thing to receive DTV with. Most DTV
is broadcast in the UHF band. Go to www.antennaweb.org to find a
list of the DTV stations in your area. You will also see what
channel they are transmitting on. (just because a TV station
identifies itself as 'channel 12' doesn't mean that it is transmitting
on the actual channel 12 frequency. There have been a lot of
shuffleing around of the frequency assignments as part of this
DTV conversion.). Antennaweb.org will also tell you the distance
and direction to each TV transmitter with a color code indicating
the type of antenna you will need.

Armed with this information, you can set up a proper antenna.
In my case, I went from rabbit ears (not very good) to a cheap
set top loop (not much better). Then I yanked the loop and cobbled
in a bowtie (getting better). Then, (I wish a took a picture) I
cobbled up a hand bent bowtie out of 12ga wire and attached it to
the top of the commercial bowtie. I finaly built a dual bowtie
setup that can be seen here:
http://mysite.verizon.net/g_reeder/Content/DTV_antenna.html
Works very well for me. YMMV.
There are other designs for DTV antennas on the internet. But

instead of just randomly trying antennas, got that info from
antennaweb.org so you know which dirrection to point the thing.

That does suggest that the signal is inconsistent - possibly it's
weak, over-all, or possibly it's subject to momentary dropouts due to
multipath reflections from moving objects (airplanes, trees, etc.).

If you're in an urban area, multipath problems are likely to be at the
heart of your problem.

Moving the rabbit-ears around to different positions will give you
some amount of gain and inteference rejection... you might find a
position which gives you a more stable result on one or more channels.

> The bedroom is on the second floor. I looked at
>amplified indoor antennas at Target and they sell for $20 to $50. The
>non-amplified is $18 (only one they have).
>
>Do most go to an amplified antenna or use an outside antenna?

As a general rule, I don't favor amplified indoor antennas. The
amplification usually doesn't buy you very much, since the front-end
section of the TV set has quite a lot of gain/sensitivity. The
antenna's own amplification will simply "replace" some of the
amplification in the TV (to no particularly good end), it will add
some amount of additional noise, and it may be subject to
strong-signal overload. Antenna-based amplifiers won't do anything to
help multipath problems, or noise problems from nearby interference
sources.

Indoor antennas may work well, or very badly. A lot depends on the
building construction. In some wood-frame buildings, they can work
fine. If the outer walls are stucco (with embedded chicken-wire), or
if the walls have foil-backed insulation, they may work very badly...
the building acts as a partial Faraday cage, and blocks most of the
signal.

> I just took
>down my old big outside antenna 3 years ago as we have Comcast cable in 3
>rooms. Comcast cost $$$ for each set up and add more wires to the house. I
>also assume the signal gets weaker the more I add.

For good TV reception, a reasonable-sized outdoor antenna on a mast is
hard to beat. Getting the antenna up into direct line-of-sight of the
transmitter/tower can help eliminate all sorts of reception problems.

If you can't arrange a roof antenna, then a smaller beam antenna
located in the attic might be a workable second choice.

Yes, when you feed a signal down the coax into the house, and split it
among several rooms, the signal in each room is weaker than if you fed
the antenna output directly to a signal room. This is actually one of
the situations in which an antenna amplifier can help: it makes up
for the losses in the signal-division process and in the coax.
Ideally, the amplifier is located close to the antenna, before any
long run of coax and before any signal-splitter.

Be careful, though. Many inexpensive antenna amplifiers (mast-mounted
or part of a splitter / distribution box) use only a simple
one-transistor amplification circuit, and can be prone to problems
from strong-signal overload. If you're located near a TV transmitter
(or a ham operator, CB'er, police/fire station, AM broadcast station)
a strong signal from the nearby transmitter can saturate the
amplifier, pushing it into distortion. The resulting signal on many
channels can be worse than if there was no amplifier at all.

I put rabbit ears on top of a cabinet, extended 'ears' all the way out,
put the 'ears' down flat (dipole) and turned broadside to TV transmitter
area. Best reception other than outside antenna.

RF blocking was used by both sides as a "burglar alarm" to detect
naval vessels passing through narrow straights. Germany tried to get
such a system working across the Straits of Gibraltar, but were foiled
by Spain's failure to cooperate.

Radar was officially "invented" in 1935 when Watson-Watt was asked by
the air ministry to calculate the possibility of using RF as a "death
ray" to cook an airplane pilot in flight. Some calculations were
performed which quickly determined that it was impossible. However,
he suggested that a similar system could be used to detect the
airplane by combining the range finding of ionospheric layers
techniques and the direction finding techniques used to detect
thunderstorms. At the time, there were also proposals for aircraft
detection using infrared and sound detection. Not wanting to lose
their funding, it was agreed that RF reflection was a good idea and
that research should continue on this different path.

> I switched.

But sometimes the circuits in the TV pick up TVI directly. In my unfortunate case, a big tube Sony, circa 1995, is on a digital cable box that outputs S-video/stereo audio to the TV. When I put antennas too close to the living room, I caused analog TVI in the form of SSB "wah-wah" in the audio, with flashing and streaking in the picture. (Had I been getting in at RF channel frequencies, digital would have shown tiling and audio dropout, which it didn't.) I filtered the heck out of those three cables and it only helped a little. I think the internals of the set are the receiving antenna(s).

I don't see a Faraday cage for a 35" TV in my future.
She-who-must-be-obeyed wouldn't like it, either.

That changes things for me! I didn't know the term "microwave rover" was
being applied to amateur radio. I never heard it before and I wrongly
thought you were talking about work -- traveling as a microwave installer.
My bad.

I am absolutely a believer in "Let's try it!" Some very good times have
come as surprises.

You don't even need to put them all the way out. If channels 2-7 are vacated in your area, then you only need to have them out about 18 inches.

507. Detecting the high def TV for the Google Lunar X Prize.

Newsgroup: rec.radio.amateur.antenna
Date: 2009-06-16 22:57:38 UTC
From: Robert Clark <rgregoryclark@yahoo.com>
Message-ID: <609fd5d7-b15e-4bf1-a5c5-60c4c68cc367@e21g2000yqb.googlegroups.com>
Source record: 14619
Cross-posted to: sci.astro,rec.radio.amateur.space,rec.radio.amateur.antenna,sci.astro.seti,sci.physics

On another forum there was debate about whether the requirement of
"near real time" high definition video transmissions was achievable
for a such a low-cost mission.
It would certainly be doable if the receiving antennas on Earth were
the large radio antennas used for space communications with
interplanetary probes or those radio antennas used for radio
astronomy. This is evidenced by the fact that the Kaguya(Selene) lunar
orbiter mission was able to send high definition video to a large
receiving dish radio antenna. And also by the fact that DirecTV sends
high definition video to only 2 foot size antennas from geosynchronous
orbit; so 10 times larger antennas would be able to receive such
signals from a 10 times larger distance at the Moon.
However, I was wondering if it would be possible to detect this using
amateur sized equipment at such a large distance. Usually for
receiving high data rates you used transmissions at very high
frequencies, as higher frequencies can carry more data. For instance
both Kaguya and DirecTV transmit the high def video at gigahertz
frequencies.
However, for the system I'm imaging I'm thinking of using much lower
frequencies, and necessarily longer wavelengths. What I wanted to do
is transmit at decametric wavelengths. High data transmissions rates
would be achieved by making it be pulsed in an on-off fashion at high
intensity but at a rapid rate.
On that other forum the data rate required for high def TV was given
as 256,000 bits per second. So I wanted to make these transmissions be
pulsed at this rapid rate at wavelengths of a few tens's of meters.
My decametric wavelength requirement was because of the fact that
high schools and universities have programs for detecting radio
emissions from Jupiter at these wavelengths:

NASA's Radio JOVE Project.
http://radiojove.gsfc.nasa.gov/

The Discovery of Jupiter's Radio Emissions.
How a chance discovery opened up the field of Jovian radio studies.
by Dr. Leonard N. Garcia
http://radiojove.gsfc.nasa.gov/library/sci_briefs/discovery.html

These school and university receiving antennas on Earth consist of
dozens to hundreds of vertical dipoles of lengths at the meters scale
to correspond to the radio wavelengths. Some questions I had: how
intense would the pulse have to be on the Moon to be detectable from
the Moon above background noise for a detector on Earth of say a few
dozen dipoles? Could this be done for the transmitter of power of say

a few hundred watts for a low cost, low weight lander mission? Could
the transmitter antenna on the moon be only a few meters size for the
low weight requirement?
A secondary purpose I had in mind was a pet project of mine involving
linking these many school receivers to form a global telescope at
decametric wavelengths:

From: rgcl...@my-deja.com (Robert Clark)
Date: 23 May 2001 11:15:06 -0700
Subject: Will amateur radio astronomers be the first to directly
detect extrasolar planets?
Newsgroups: rec.radio.amateur.space, rec.radio.amateur.antenna,
sci.astro, sci.astro.seti, sci.space.policy
http://groups.google.com/group/sci.astro.seti/browse_frm/thread/c0018b68662c14e9

The long wavelengths should make the requirements for accurate
distance information and timing synchrony between the separate
detectors easy to manage even for amateur systems. Using this method
might make the detection achievable even if the power or transmitting
antenna size requirements are not practical for a low cost, low weight
lander on the Moon for an individual detector on Earth.
The recent achievement of real-time very long baseline interferometry
should make it possible to integrate these separate detector signals
in real-time as well:

Roving (or "rovering", nobody seems to know which it should be) is a
great aspect of VHF & up operating. It's taken me to some beautiful
sites where it was wonderful to be in the outdoors enjoying the weather
and the radio at the same time -- except in January ;-)

Rover is a separate category in the ARRL and other VHF & Up contests.
See, e.g., http://www.arrl.org/contests/rules/2008/jan-vhf-ss.html

Us hard-working, dedicated operators :-) get special consideration when
computing scores.

As a member of the club that has taken roving to new heights over the years, I can safely say that it is indeed "roving".

The rovers got us as many 10GHz grids this weekend as the sum total of the previous 11 contests. And they don't play the games that some of the east coast "owned" rovers do. The rovers in the upper Midwest will, and will try to, work anyone and everyone. Cooperation amongst competition makes for a better contest.

And thank you for roving, something I always take the time to say to anyone signing /R during the contest. You guys are definitely the hard working and dedicated operators out there. I just wish roverlog wasn't so weird and flaky.

Don't forget that DirecTV radiates a LOT more power than a typical deep space probe. AND they often have a higher gain antenna. A geosync relay satellite might have 96 TWTAs, each several hundred watts, on it, feeding a very clever multiple feed dish which is many meters in diameter (look at Thuraya, for instance).

> However, I was wondering if it would be possible to detect this using

There's a moderately active Amateur DSN group that listens for things like Chandrayaan or MRO using relatively small dishes (1-2 meters).

The choice of higher frequencies isn't because it carries more data. It's because a higher frequency allows you to get more gain with the same physical antenna size. Double the frequency, and your antenna gain goes up by a factor of 4, at both ends of the link.. a total of 12 dB improvement in SNR, for the same transmitter power and receiver noise figure. And, there's more spectrum available up high.

> However, for the system I'm imaging I'm thinking of using much lower
> frequencies, and necessarily longer wavelengths. What I wanted to do
> is transmit at decametric wavelengths. High data transmissions rates

How high a data rate? If you're at 30 MHz (10m lambda), you're not going to be pulsing at 10 MHz, or you're going to be generating a signal

that extends from 20 to 40 MHz (and then some). You need a low symbol rate with lots of bits per symbol, which in turn means you'll need lots of SNR.

> On that other forum the data rate required for high def TV was given
> as 256,000 bits per second.

HDTV, as carried on broadcast TV, is 19.8 Mbps. If you're happy with a lower frame rate, or can do a lot of frame/frame compression, you can get it lower.

So I wanted to make these transmissions be
> pulsed at this rapid rate at wavelengths of a few tens's of meters.

Any one school only has a couple dipoles up.. the gain is quite low.

Some questions I had: how
> intense would the pulse have to be on the Moon to be detectable from
> the Moon above background noise for a detector on Earth of say a few
> dozen dipoles? Could this be done for the transmitter of power of say
> a few hundred watts for a low cost, low weight lander mission? Could

> low weight requirement?

How technical do you want to get? There's a book about space telecommunications system design available for downloading from JPL (http://descanso.jpl.nasa.gov/ somewhere on that site)

Here's some basic numbers you'll need:

Free space path loss in dB = 32.44 + 20*log10(distance in km) + 20 *log10(frequency in MHz)
That's between isotropic antennas (0dBi)..

Antenna beamwidth is 70 degrees/ (diameter of antenna in wavelengths)
Antenna gain is 27000/(beamwidth^2)

A typical receiver noise figure (after figuring in losses in coax/waveguide, etc.) is probably 3dB.

kTB noise is -174 dBm/Hertz * 10*log10(bandwidth in Hz)

> A secondary purpose I had in mind was a pet project of mine involving
> linking these many school receivers to form a global telescope at
> decametric wavelengths:

Coherent combining would be a challenge, because of ionospheric
variability at HF, not to mention the other challenges.

Look up LOFAR or the SKA (Square Kilometer Array) for a fairly well
funded scheme.

Wow. 96 TWTs with several hundred watts each. From a satellite. And
what's the efficiency?

So these are powered by what? Small nuclear reactors?

Certainly not solar panels.

Yes. OP said "near real time," which I take to mean "OK to drop some frames," like the satellite video phones the reporters use from the boondocks. Thus, high-def can be confined to a lot lower bandwidth if you don't mind seeing compression artifacts as each frame is being built on the screen.

I have a contemporary example: KABC-DT, Channel 7 Los Angeles is high-def on 7-1 AND high-def on 7-2, with a service called Living Well. See http://livingwell.tv/Welcome.html.

Living Well is apparently getting a skimpy bitshare, as compression artifacts are obvious, especially on scene changes and motion, whereas ABC programming on 7-1 is just beautiful. Living Well is very good, sharp HD, but you can see details being "painted in" for a quarter-second after a scene change.

Not all will necessarily be on at the same time.
Typical narrow band coupled cavity TWTAs can get over 50% efficiency
(DC in to RF out)
Yes Solar Panels..10kW would not be unusual.

See, e.g., http://en.wikipedia.org/wiki/ASTRIUM_E3000 ... 14 kW of
power from 45 m^2 of solar panels and 4500kg of satellite..

This is so far beyond what is used in the scientific space program
it's mind boggling. But, hey, out of the $1-2B cost, the TWTAs are
probably only 5-10% of the total, and there are definitely quantity
discounts.

You will never get uncompressed HD video transmitted from the lunar surface. And really, there is no need for it if the compression is handled right. Only a few people I know can do that part.

Since the image is mostly repetitive, a low bitrate can be achieved which should allow for a very good signal level path budget. this would make for a higher energy per bit and a more reasonable earth station within the budget of amateurs. (if thats the goal) To achieve a very low bitrate, such things as Pre/post-distortion to utilize less bits, (black gamas) using extremely long GOP structures and since the action of the video is extremely slow and repetitive, a slow frame rate such as 1fps. These can be counteracted at the receive station with software without effecting the total image resolution.

The image resolution is where the wow factor is anyway! :-)

My *guess* is that whomever would put a spacecraft on the lunar surface would only have one high speed datapath back. The HD transport stream would be muxed in with the other data elements of the spacecraft on a

transmission system without consideration for amateur reception. Perhaps encrypted if a commercial entity is paying for the broadcast rights.

There's a fairly complex trade. For a lunar mission, the scene is
going to be pretty static, just shifted. (not like there's a baskeball
team doing a fast break in the field of view), so it should compress
well, given a suitable algorithm.

The challenge is that compression (especially good compression) takes
computational power. So you have a tradeoff: do you spend you joules
on compressing the images and radiate less RF energy, or do you
compress less, and use a bigger power amp. There's also a mass
tradeoff.. big amp or big antenna. The big antenna needs more
accurate pointing, which increases complexity. Or the trade of
frequency selection, higher frequency means more antenna gain, but
usually lower efficiency in the PA and higher NF in the receiver end,
as well as higher probabiliity of weather related fading.

And even there, because Moore's law means that semiconductor
technology is always advancing, the tradespace is shifting towards
more processing (because it gets cheaper in size, weight, power, while
power amps are pretty much at the physics limits)

This is, of course, "rocket science".. or more properly, spacecraft
system engineering. It's straightforward, for the most part, but non-
trivial. Pick your requirements, define the tradespace(s), try
configurations and see what happens.

Here's a back of the envelope link budget for a 500E3 km link carrying 1 Mbps

Let's assume 2GHz for the working frequency (not necessarily a good choice, but somewhere to start)

Free Space Path Loss from Moon to earth, between isotropic antennas = 32.44 + 20*log10(500E3) + 20*log10(2E3) = 32.44 + 114 + 66 = about 212 dB

Assume an antenna 2m in diameter at one end (moon end)
lambda for 2GHz is 15cm, so the antenna is 13 wavelengths in diameter
Beamwidth will be about 70/13 = 5 degrees.. OK, because Earth is 2 degrees wide from the moon, so you can just point at the middle of the visible earth.

Assume an antenna 10m in diameter at the earth end. Beamwidth will be 1 degree, twice the visible lunar disc size, so you can just point at the moon, generally.

Gains of antennas
2m @ 2GHz = 30dB
10m @ 2GHz = 44dB

Preceived at Earth = Ptransmitted +30 - 212 +44dB = Ptransmit -138dB.

Assume transmitting with 10 Watts or +40dBm..
Prec = -100dBm

Now, let's look at the receiver:
Power Spectral density of Noise is kT+NF.. kT is -174dBm/Hz and a decent NF might be 2dB (allowing for some plumbing losses, etc.

-172 dBm/Hz

Eb (energy/Bit) = -100dBm -60dB (1Mbps) = -160dBmJ

So, Eb/No is about +12dB... If you allow 2dB for implementation loss, that gets you to 10dB, which will get you a BER of 1E-6, which isn't terrible. Coding will improve it, etc.

Take home message:

10W at 2Ghz with reasonably sized antennas at moon and earth can carry 1 Mbps.

Scales linearly with data rate.. You want 10Mbps, you need 100W. Or bigger antennas.

If you ground all the inputs, do you still have interference? Common mode
is the usual problem. Given the number of DVD-players, VCR's, surround
sound systems, switchboxes, Media Center computers tied in, you could easily
have more problems than which of seven remote controls to look for.

I guess this analog-to-digital transition is going to be another your-
mileage-may-vary situation, but I do hope it works out for most folks.

Did you also check out the power wiring as another possible antenna? If
proximity of the RF source and the TV system was a factor, I think I'd
worry more about the susceptibility of the receiving system more than the
cleanness of the RF source, and RF getting in by the power cord used to
be a common problem.

two biggest reasons:

Since binaries are stored on Netnews providers servers, they became one
of the most identifiable providers of Kiddie porn.

Netnews has a generous supply of crazies, some of whom post in here,
with a few posters managing to make thouhsands of posts every day. Most
with almost the same content.

It is no wonder that Netnews is being dropped like a hot potato among
ISP's. A huge liability if they were to carry binaries, and probably the
source of thousands of complaints if only carrying the groups.

Many ISPs have canceled and are canceling Usenet service
in order to be politically correct. Instead of trying to
define and filter politically incorrect newsgroups, they
are simply shutting down Usenet servers.

Chiming in late on this one...

Mythical attributes aside, I believe the real reason that ladder line has become more popular is:

1. Almost all rigs are All HF band these days.

2. Many people have just one antenna they can put up at any given time. Whether it is space considerations, maintaining a low profile or keeping the XYL happy I remember the discussions with my wife when I wanted to put up the HF vertical. "Why do you need two antennas?" "Are you going to transmit two signals at the same time?". Twasn't easy, and a lot of Hams might lose that argument.

So assuming it is a doublet, and I wanted to run 80 to 10 meters, I'd put up much wire as I could, not mess with coax, just run ladder line to a window panel, then into the house, into a tuner that can handle balanced line. And pay attention to the lengths that might make for trouble in matching.

An unfortunate smear on the east coast in general, especially since I am from there. It is well known who the stations/clubs are that get away with it. I would make a disparaging remark about the blessed League caring about cheating here, but it would offend the masses.

I think the reason they are cancelling is because they do not want to
hear all the comments about their lousy service, plus charging
customers in the southeast higher prices than in non bellsouth areas.

I cannot tell you about the difference, as I never had the opportunity to test them both in the same place. My 18AVQ was in an urban backyard in Richnmond BC and worked adequately but was not really stellar, possibly because of local noises from old tube type TV sets still very common at the time.

The 18AVT was in a salt marsh in a remote location offshore in the Atlantic well away from housing. I worked all continents on 75M SSB the night after I put it up!

If your antenna is balanced, it would probably be better to simply split
the ladder line onto the center conducters of two identical short coaxes
and then run ladder line inside to your tuner. If you MUST ground the
shields that's OK and you can use lightning arrestors on both coaxes. But
remember, no lighning arrestor is as good for protecting equipment as a
foot or two of air. Disconnecting during thunderstorms is solid policy!

Well, they certainly don't make money on Netnews.

But I still think that if the authorities came to any of us, telling us we had something illegal stored on our servers, probably 9 out of 10 of us would drop it in a heartbeat. Why would I keep something that is only a liability or at best, a nuisance?

I mean even from a moral point of view, the only control you have is shutting off the binaries, all of 'em, because the bad guys don't limit their posts to the groups you might expect them to. And while you can't be responsible for everything posted on your servers, you sure can after you know it's there and don't remove it......

Then the problem is that after getting rid of the binaries, the regular newsgroups can end up with a little guilt by association, even if they aren't doing anything illegal. So they get tossed too.

All contesters cheat except for me and thee....

So if I go roving, and I don't belong to one of these clubs, will they
not talk to me?

And if they are cheating, and it's documented, why hasn't anyone
submitted proof, and get their sorry butts DQ'ed?

Takes lots of people to cheat, those cheating, and those putting up with it.

Sorry for the rant, but as a person who runs a contest, I get many, many
accusations of people or clubs cheating, and precious little to support
that. Most of the time the accuser pops up with great angst, describing
the terrible situation, the nefarious cheaters, and often the complicity
of the contest organizers. Then when pressed for proof, the reply is
usually "Gee, I don't want to start anything!"

Not sayin, I'm just sayin'...

Sounds a little backwards. The Ladder Line should transition to coax
(balanced as you pointed out) inside to hopefully reduce RF in the shack.
An arrestor outside in addition to disconnecting from equipment will avoid
arcing in the shack at least. You have to be there to even remember to
disconnect.

540. Re: AT&T Usenet Netnews Service Shutting Down

Cecil,
Just something to think about. I signed up with TeraNews last night. I'm sure part of the problem was me just not understanding 'their' way of doing things, but there were problems. Couldn't get a satisfactory answer to too many questions, and finally had to cancel the subscription.
Did some checking to see if anyone else had these sort of problems, and it seems to be fairly common. I honestly can't say TeraNews is a bad choice, but it was certainly the wrong one for me.
As for why AT&T decided to quit newsgroups? So they can make a buck on it, of course! AT&T and 'Ma Bell' do not have a good odor around here, even with their employees.
- 'Doc

I also had problems because I didn't RTFM where they
say the user name has to have @teranews.com appended.
After fixing that problem which was all mine, it has
been pretty reliable.

Teranews is apparently a good NSP if you want to flood the newsgroups
with abuse.

Rumor has it that they are not quick to control their
bad apples. Of course, some on this newsgroup consider
my tendency to quote technical references to be abusive. :-)

Or, put up as much wire as you can, put an autotuner at the feedpoint,
and run coax back to the shack.

probably a six of one, half dozen of the other, depending on what you
already have, what kind of support structures you have (if you are
putting up an inverted V, then supporting the weight of the tuner isn't
an issue..), etc.

>

If you have a direct hit, a one foot air gap isn't necessarily going to
do you much good, unless the antenna end of the gap is on the ground
surface. (i.e. the wire going from where the coax ends to your
lightning dissipation ground has some non-zero inductance/resistance)

If you're worried about induced voltages from adjacent strikes, then a
good transient suppressor will help, but almost all suppressors have
"let through" voltage that is above the damage threshold for, say, a FET
front end. Depends on what your equipment sensitivity is.

Shorting the input of the radio and tying it to chassis ground.. that
WILL protect the radio.

546. Sunspot news

It sounds as if there may be an explanation for the current sunspot deficit. Ok, not an explanation, but something that perhaps correlates with sunspot production. And if correct, good news.

That whole "guilt by association" sure is a slippery slope. I
wouldn't worry about it. The new administration is giving out miranda
rights to everybody.

First, not all contesters cheat. My experience is few VHF and up
contesters cheat.

Second, the rovers are the key to the cheat. Fixed stations love to
work rovers because of the point and grid benefits. The cheating is the
rovers who won't work anyone but the mothership.

Third, it's not documented since no one will publicly admit to it, which
should be obvious. Privately is a different matter.

The cheaters are known. Very well known in some cases.

Thanks for the info. This at least should be doable with receiving
antennas operated by universities.

for most people the feedline won't be that long so just put up the inverted
v, wind a coax choke at the feed point (or not) and just run it back to the
shack and use the tuner in the rig.

We're getting a bit off topic here, but ....

The issue is with "captive" (or "owned", as tom said) rovers who will communicate only with the fixed club station. The rovers don't get a lot of benefit from it, but it can really pump up the score of a fixed station by getting additional grid multipliers.

What documentation may exist is in the hands of the club rovers. Proving that someone is doing this is well-nigh impossible. I suppose a contest manager could do it by examining all the rovers' logs he gets. But I don't expect that would be an easy job. And the contest managers are supposed to be having some fun too :-)

So I agree that a contest manager needs proof before acting on any accusation of cheating, but in this case I doubt that he's ever going to get it. (No comment on other forms of cheating.) Nonetheless, that doesn't mean that it isn't going on. We just can't do much about it. And those putting up with it should not be lumped in with those who may be/are doing it.

I hope the squabbling you're in the middle of doesn't dissuade you,
Mike. Keep on keepin' on. Please.

Speaking of autotuners, I just got my MFJ933, and have been working
with it this last week. MFJ has an interesting reputation, but I have to
say they pretty much got this one right. For $224, it is one impressive
piece of hardware/programming.

I run my window line directly to the tuner, which was a big selling
point. NOt many other auto tuners have that feature.

Construction was quite acceptable, performance has been fine so far, and appearance good with only one exception. One of the front panel's letters had a little rub mark on it. No biggie, just cleaned it with an eraser.

The analog meter is a little small, but the whole unit would have to be made bigger to put in a larger one, so that was a tradeoff. It also has the digital readout, so I find myself looking at the analog meter for initial reference on a frequency, then at the readout after that. It has a lot of other features that I'm still learning.

I give the unit an A, at least on my experience so far.

In this post I suggested using DirecTV's and other satellite TV
companies receiving dishes for SETI:

Newsgroups: sci.astro.seti, sci.astro, rec.radio.amateur.space,
sci.physics
From: rgregorycl...@yahoo.com (Robert Clark)
Date: 7 Feb 2005 15:07:03 -0800
Subject: Could DirecTV satellite dishes be used for the Square
Kilometer Array - and a more radical proposal[Re: Can DirectTV-type
satellite dishes be used for SETI?]
http://groups.google.com/group/sci.astro.seti/msg/e425e5339227855a

In the discussion in that thread there were mentioned several
problems with that proposal (possibly fixable with some expensive
retrofits) but one big problem is that satellite TV is not designed to
be two-way. Some satellite services are two-way when they are also
used for internet access, but this is a much smaller proportion of the
satellite TV subscribers.
However, instead of using the satellite TV dishes, we could use
individual dipole antennas attached to each house. You would need to
communicate high data rates for the signals detected so you would need

broadband internet access for this.
These dipole antennas as per the Radio JOVE project are just simple vertical wires so could be attached to the house when the installer is connecting the wiring for the broadband. Possibly you could use the same external wiring as for the broadband but that might cause interference with the internet signals.
As shown on the Radio JOVE page the receivers for these dipole antennas are quite simple so would contribute minimally to the cost of installation. You do need accurate positional determination and timing synchrony for each receiving system to do the very long baseline interferometry, but at these decametric wavelengths this would be easy to do with GPS receivers carried by the installers. Over time you could keep the systems in synchrony by timing stamps accessed over the internet.
I suggested before using 10 million dipoles world-wide for detecting Jovian-sized planets close in to their primaries out to perhaps 10 light-years. According to this page, over 16.6 million new broadband internet users came online just in one quarter this year alone, bringing the number of broadband users world-wide to 429 million:

More people worldwide are subscribing to high-speed Internet connections.
China and other Asian countries among the growth leaders.
http://www.nationmultimedia.com/2009/06/17/technology/technology_30105358.php

New broadband subscribers would automatically get the dipole antennas. At the rate of increase of broadband subscribers, it would only take 3 months to reach 10 million separate dipoles. If each installer when setting up a new system, also retrofitted an another existing broadband system, then you could reach the full coverage of all the broadband subscribers dipoles in 6 years.
The number of world-wide broadband subscribers will be 500 million by 2010. At current growth rates it would be 900 million within the 6 years it took to equip each broadband subscriber system with one of the antenna dipoles. This is nearly two orders of magnitude better sensitivity than a 10 million dipole system. You could detect out to 100 light-years, opening up many more stars to the possibility of detection.

The MFJ-933 is a manual loop tuner according to their catalog. Which ever one you are using sounds nice, and is worth a look, but I don't think it is a MFJ-933.

It won't be a large change, but there will be some difference.
I'd rather have the ends at 30 ft vs 20 ft. On the low bands
using a fairly low antenna, I think the ground losses slightly
increase as the ends come closer to the ground.
I've tested this in the real world on 75 meters.
In general, the higher the ends, the better.
But saying all that, it will still work pretty well if you do
drop the ends.

Lowering the ends as you describe will have only a small effect on the band
you mention. You can expect the feedpoint impedance to change a little (and
that might be in our favour).

The requirement was to cease high power broadcasting in analog, not
cease broadcasting in analog.

In the LA area there are still 7 stations running the conversion
infomercial in low power analog.

RF channel 2 is not slated to disappear, it just won't be used by
as many stations as before.

if its tuned with a matchbox already you don't need to make it a bit longer
to reach the mars frequency. the 'bit' longer probably won't improve the
performance any more than lowering it will hurt the performance as long as
the rig is happy with the match from the tuner.

572. Antenna Orientation Question

Hi,

Figure that if anyone would know, it would be you folks.

Seem to get contradictory results, so I thought I'd ask you experts out there. For receiving digital TV with a a simple, cheap, R/S indoor rabbit ear antenna
Works fairly well.

For rabbit ears indoor, what is the theoretical best orientation toward a single station ?

e.g., a plane encompassing the two ears would best be pointed toward the station, or the plane
should be perpendicular to the direction of the station ?

b. For the UHF loop:
the plane of the loop of the antenna should be pointed toward the station, or perpendicular to it ?

I realize it might be hard to visualize the plane that I refer to, but frankly don't know any other way of
describing orientation.

Perhaps one way would be to say if the rabbit ears are both the exact same distance to the antenna,
or if they are in a line with one right behind the other ponting to it ?

Would be more or less the same kind of description I guess for the UHF loop (parallel to the rabbit ears plane, or at 90 deg. to the rabbit ear plane) ?

Perhaps you know of a pix on a website that answers my question by showing a pix of how it should be pointed ?

Much thanks,
Bob

While that is true, I don't think it answers his question. The FCC created a "nightlight" program where one station in each market is keeping their analog transmitter going for a while to help those caught by the transition. As the OP stated, they are airing a DTV infomercial in English and Spanish until the real end in a few weeks. WKYC in Cleveland's analog signal will remain on until June 26th. I will guess the Reno station is doing something similar.

In general, the "plane" of the antenna should be pointed toward the
station. For example, if the station is north of you, the elements
(or the sides of the UHF loop) would be pointing east and west. Of
course, rabbit ear antennas are one huge compromise and should be

pointed however they work best whether or not it makes sense or fits with theory. The desired signal might just be reflecting off your refridgerator so aiming that way is best at that moment.

Soory if this is a duplicate... I sent a similar response a few
minutes ago that showed up as no longer available. I'm not sure what
that means.

Anyway, that station is probably part of the FCC's nightlight program.
It will go off around the end of June. ...Pat N8CQV

577. Horizontal Dipole - zero degrees elevation

Newsgroup: rec.radio.amateur.antenna
Date: 2009-06-20 13:44:14 UTC
From: greenpjs@neo.rr.com
Message-ID: <mjop35p3m3h9g178q2nav9oe1d5l6t2564@4ax.com>
Source record: 14589

Hello all you antenna experts,
I have been a ham and an engineer for a long time, but I have never delved into antenna theory. So, consider me a newbie for this question.

I recently was helping a friend set up a crude antenna to connect to his DTV converter box following the June 12th conversion to DTV. I explained that a dipole was a simple antenna that could be used. He was very interested in the subject so the conversation soon turned to theory. I explained the 468/freq formula and eventually mentioned EZNEC. I have never used EZNEC myself so I downloaded the demo version and now have all of 24 hours experience with it. I started with the included backyard 20 meter dipole. I was surprised that there was no radiation toward the horizon. I figured that I was too close to the ground so I changed the frequency to 491 MHz (RF TV channel 17) and shortened the dipole accordingly. Still no zero degree radiation. I raised the dipole to 100' - then 1000' - then 10000' - still no radiation at zero degree elevation. I then found this in the help section:

Because the far field sky wave from a horizontally polarized source is zero at a zero elevation angle for any ground type, and a vertically polarized source produces zero sky wave for any finite-conductivity ground, attempts to calculate a 2D pattern without the ground wave component under these conditions will result in an error message.

Sure enough, changing to free space instead of a real ground changed the pattern to what I would have expected. I would have thought being many wavelengths above ground would be just as good as free space, but EZNEC doesn't think so. Am I missing something? Does a horizontal dipole really have a problem seeing a broadcast TV transmitter out on the horizon? Thanks. ...Pat

Not easy, not for the precision required.
You need not only precise time (straightforward), but also precise
location (not so straightforward)

You're interested in roughly 20MHz, as I recall. Wavelength of 15
meters. In time, about 45 nanoseconds.

Let's start with a real relaxed requirement, comparable to the mirror
flatness for a telescope of lambda/14. That means a time knowledge
of about 3 ns and a position knowledge of 1 meter, in absolute terms.

Typical GPS receivers that have a 1pps output are good to about 20-30
nanoseconds. Using that to discipline a quartz oscillator, you can do
a bit better, but it's non trivial to get to the 1-2 ns range.
Remember, you're also planning on integrating over time, so you have
to hold that tolerance for a long time.

It would be difficult to determine your position to an absolute
accuracy of 1 meter, much less the phase center of the antenna (which
will change as a function of the angle of incidence, quite
substantially, unless you're putting those dipoles up 100s of feet in
the air.

Using this method
> > might make the detection achievable even if the power or transmitting

> > The recent achievement of real-time very long baseline interferometry
> > should make it possible to integrate these separate detector signals
> > in real-time as well:

<snip>

You need to go beyond looking at press releases from radio
astronomers.

> However, instead of using the satellite TV dishes, we could use
> individual dipole antennas attached to each house. You would need to

> same external wiring as for the broadband but that might cause
> interference with the internet signals.

Radio Jove uses a pair of horizontal dipoles connected together to
create a single narrower lobe pointing up.

> As shown on the Radio JOVE page the receivers for these dipole
> antennas are quite simple so would contribute minimally to the cost of
> installation.

Who's paying, and how minimal? I don't think so.

You do need accurate positional determination and timing
> synchrony for each receiving system to do the very long baseline
> interferometry, but at these decametric wavelengths this would be easy
> to do with GPS receivers carried by the installers.

No they can't. You need position accuracy of sub-1 meter accuracy,
and that isn't achievable by simple handheld devices, like your Garmin
E-trex, etc. A surveyor using a survey GPS system can get there,
although absolute position (relative to, say, the center of the earth,
or some standard datum) to 1 meter would be very challenging.

There's also the not so little problem of tidal bulge. Your position
changes in absolute (relative to a stellar reference) terms several
tens of cm. On top of that, tectonic plate movement is on the order of
several cm/year, which is in the same general ballpark as your
accuracy requirement.

To do the kind of large area combining you're contemplating requires
geodetic quality surveying or some form of in-situ calibration using
known sources (which the folks doing LOFAR and SKA have thought
about). When DSN does accurate interferometric measurements of deep
space probes (a process called Delta DOR) they use a "common view"
quasar as a timing reference, because the Hydrogen maser normally used
for VLBI kinds of things isn't good enough.

Over time you
> could keep the systems in synchrony by timing stamps accessed over the
> internet.

NTP over the internet is only good to tens of milliseconds. You need
nanosecond precision.

> New broadband subscribers would automatically get the dipole
> antennas. At the rate of increase of broadband subscribers, it would
> only take 3 months to reach 10 million separate dipoles. If each
> installer when setting up a new system, also retrofitted an another
> existing broadband system, then you could reach the full coverage of
> all the broadband subscribers dipoles in 6 years.

Let's see, leaving aside the surveying and time synchronization
problems, in economic terms this is a non-starter. Say it costs $100
for each "station"... that's a billion dollars for your 10 million
stations. And $100 is a very, very low cost estimate, because
installer time isn't free (probably about $25/hr with all benefits,
insurance, equipment, added in).
BTW, if you really want to do something like this, think in terms of
an addon to a cell site. They already have to have nanosecond
precision timing and surveys in order to do E-911 position
trilateration.

> 100 light-years, opening up many more stars to the possibility of
> detection.

I think the 100 billion dollars could be better spent in other ways,
if looking for planets is your goal. Check out Terrestrial Planet
Finder (TPF) for one approach.

Hi, Jim.
Didn't look up your QTH, but there is another possible answer.

I live in Central Oregon. We don't have a house TV connected to an antenna, I went out to the 5th wheel trailer yesterday to see what analog TV was still available to us and discovered more than a dozen were still on the air. They were all signals from either repeaters or translators located on a mountain to the East of us. The FCC did not require any repeaters/translators to go to digital. So some of the signals you are noticing may be from this source.

None of the analog TV signals I found were on VHF, however.

Paul, KD7HB

Dear Jim NN7K:

In this area, Channel 25 continues to inform those who have yet to convert.

The station in your area that is performing the same service on channel 2 must be KTVN with an analog station some 39 km from you (and digital signal on channel 13 some 33 km from you).

I note that by next month, as many as 12 digital stations might remain on channel 2 in the US. FCC records are not clear, but it is expected that the actual number will be smaller. What is clear is that many, many mostly low power TV stations will continue to use channel 2. Within 200 km of you, a 4 watt station at 163km (165 degrees) and a 3 kw station at 169 km (284 degrees) are expected to continue.

It has been a mystery why any TV stations will continue to transmit on channels 2-6 and above 51.

Hi Pat,

EZNEC is presenting you with lobe characteristics that are at a very great distance (and, yet, it has no sense of skip as that would be tested in the domain of a propagation modeler). Zero degrees up to 10 degrees are minutely examined by those interested in skip, but this is not a TV phenomenon (not to be confused with ducting which can offer similar DX from great distances).

The horizontally polarized transmission has its E-Field parallel to earth. Earth is a conductor (albeit a poor one, but in comparison to free space, it is quite a short circuit). That E-Field's two potentials are being laid across that conductor during the wave propagation to that far point where EZNEC then sums up all field contributions to present you with the lobe characteristic. It stands to reason that at that great distance, the wave will have attenuated considerably - hence the low value.

Removing the short circuit (going to free space) removes this attenuation.

Paul , translators didn't have to move, or change to digital

I am just north of Reno, NV, and tho never could get good pix
from local stations (and still can't get the digi's, the HIGH
power Channel 2 transmitter (I thought) would be off the air,
on the digi conversion day-- Wrong! It is the digi cutover info
channel here, now in Reno. Someone forwarded me a list of the
Channel 2 Transmitters "Nitelighted" And there may be another
not shown, (Detroit?)

http://www.wtfda.org/images/stories/NLch2.JPG

Reason I asked, since 6 Meters is next to Channel 2, and even
with the Vestigial band filter, on channel 2, there is considerable
signal leakage in 6 meters, from this station - noise that should
dissappear after it is finally off the air.

Thanks for comments- Jim NN7K

Mac- here (should be) the list of U.S. TV stations, both former, and
their new channel assignments (in PDF format). As this list shows,
only close Channel 2 left , would be in Flagstaff, AZ.

see:

http://hraunfoss.fcc.gov/edocs_public/attachmatch/FCC-08-72A2.pdf

Note: this doesn't cover translators, nor low power stations.

Hi Bob,

The rabbit ears should be spread wide and facing the strongest signal
(as if to embrace it).

>e.g., a plane encompassing the two ears would best be pointed toward the
>station,
No.
>or the plane
>should be perpendicular to the direction of the station ?
Yes.

>b. For the UHF loop:
>the plane of the loop of the antenna should be pointed toward the station,
No.
>or perpendicular to it ?
Yes.

The plane should not extend to the source of the strongest signal; it
should be broadside to it as if to catch it all (like a soccer goal).

As for "shoulds" and the shift of emphasis away from station and
towards the "strongest signal." This is obvious from experience until
you add the knowledge of where the station is which may confound
expectation. For indoor operation, the arriving signal may undergo a
lot of reflections in the neighborhood, or within the home
environment. Hence, the relation of the antenna towards the station
may seem to be at odds when that strongest reflection comes from
another angle.

This troubling situation is reduced by raising the antenna so that the
over-the-air transmission is clearly the strongest over all
reflections. That is why we call this mode "line of sight." If you
cannot literally see the station antenna, what you are receiving is
coming to you through a myriad of paths of reflection. Obviously you
are limited in how high you can raise an antenna indoors. No doubt
you are equally experienced with the seeming caprice of aiming an
indoor antenna at a consistent well behaved signal. This is what
drives antennas outdoors and up.

592. Odd lightning effect

Newsgroup: rec.radio.amateur.antenna
Date: 2009-06-20 17:40:52 UTC
From: Bill Ogden <billogden@optonline.net>
Message-ID: <4a3d1ea9$0$22522$607ed4bc@cv.net>
Source record: 14454

It was raining heavily. I was sound asleep at about 2AM when there was a really violent KA-BOOM. It propelled me out of bed and woke me enough to check the house for lightning damage (none) and to switch my antenna to a dummy position (yes, I know this does not do much good, especially after the fact).

You know those "gift bags" (looking like a small shoping bag) that play tunes when a certain spot is squeezed? They usually play "Merry Christmas" or "Happy Birthday". One of these bags was in the bedroom, and had not been touched for months. It started playing (without being touched) just after the KA-BOOM.

A second major KA-BOOM thunder/lightning happened about 10 minutes later. The bag started playing again. Both times, the bag played a normal cycle of the tune and then quit.

There was no damage anywhere in the area and my Orion seems OK.

The OT question is what kind of antenna effect (in the gift bag) would activate it? While it was raining heavily, there was no sense of heavy humidity in the house. No other electronics were affected, as far as I could tell.

Maybe not an antenna effect at all, but the pressure wave that produced
the KA-BOOM pushed the switch.

From: "Geoffrey S. Mendelson" <gsm@mendelson.com>
Message-ID: <slrnh3q8c4.ms0.gsm@cable.mendelson.com>
Source record: 14456

I have a microwave leakage tester. It is calibrated for 2450 mHz, so it should be perfect for testing WiFi Network output power. It is calibrated in mw/cm2 (miliwatts per square centimeter). It is also ham related as I am limited to 100mw EIRP on the 2.4gHz ham band.

So I figured that I could use it by measuring the field strength at a specific distance from the antenna, and then applying a conversion factor.

Anyone have any ideas?

Thanks,

Geoff.

Lightning can do some pretty strange things. I was given a RS color computer years ago after it had been on the receiving end of a lightning strike.
Already having one of these computers I proceded to check it out by replacing the chips in my computer one at a time with the ones in the fried computer(I know, not very smart). Well at the the end of all the chip swapping my computer still worked. Power supply on the damaged computer checked OK. A closer inspection of the circuit board showd that some traces underneath the processor chip had ben vaporized. Repairing these traces yielded a working computer. How the lightning burned out these traces without frying the rest of the computer was beyound my understanding.

The "near field" analysis feature of EZNEC or other modeling program will tell you what field strength in V/m you should expect from an antenna at any specific point in space, if you're able to model the antenna with the program. Power density (mW/cm^2) will be meaningful only if the observation position is in the far field, which is very little distance away at that frequency, but the "near field" analysis is valid also in the far field. For the conversion, use the relationship that the power in watts = V^2/377 where V is the field strength voltage in volts, or mW/cm^2 = (V/m)^2/3770. Again, this measurement is made in the far field, which is typically any distance greater than a fraction of a wavelength from the antenna. If your antenna is fairly simple, the free demo version of EZNEC is adequate to do the modeling.

Dear Jim NN7K: Actually, channel 2 in Flagstaff has been off the air for
a while. KNAZ Flagstaff is digital on channel 22 and duplicates the
programming of KPNX (digital channel 12).

WJBK Detroit, which was on channel 2, is now digital on channel 7.

Outside of (mostly) low power relay stations, these are the most likely
channel 2 (digital) stations actually on the air:
KREX Grand Junction CO 800 w
WLBZ Bangor ME 3 kw
KNOP North Platte NE 16 kw
KVBC Las Vegas NV 27.7 kw
KOTA Rapid City SD 7.1 kw
KJWY Jackson WY 270 w

Looks as if the station south of you will be the most strong channel 2
source of interference (after KTVN goes off the air)..

I'm not sure what you mean. EZNEC seems to say that a horizontally
polarized dipole seems to have zero gain (-99.99DBi) at zero degrees
elevation regardless of the frequency. So far, I have only tried 14
(the 20 meter example that came with EZNEC) Mhz, 491 Mhz (TV channel
17 center), and 527 MHz (TV channel 23 center). I switched to 527
because I can actually see a channel 23 transmitting antenna from my
window. For those who may not missed my original post, I find it hard
to believe a horizontal dipole tuned to the right frequency (near 1:1
SWR with 75 ohm source) would not be able to hear a signal coming from
zero degrees elevation. In the real world, there are all sorts of
reflections off of all sorts of things that will make it work, but is
it true that there should be no signal if everything was ideal?

Richard explained the attenuation of the E-field. That makes sense to
me, but doesn't really explain the other nulls at 6 degrees elevation
and every 6 degrees above that. There are strong positive lobes at 3
degrees and every 6 above that. The plot looks like a nice flower :-)
I would think that attentuation of the E-Field would explain zero

degrees, but as elevation increased, the attenuation would decrease. The EZNEC plot looks more like it is showing additive and subtractive combining of the signal. Another reply mentioned a different program that calculated ground wave in addition to skywave. Maybe that is what I am missing. I normally think of ground wave as why VLF, LF, and MF signals travel further than line of sight, though. Does ground wave have a significant effect at VHF/UHF?

I'm still confused,
Pat, N8CQV

what you are missing is the 'real world'. eznec is probably modeling over a perfectly flat infinite surface. In the far field in a perfect world the signal along the surface is a combination of ground wave and sky wave, the ground wave decays rapidly with distance leaving the sky wave which will always be very small along the surface. now remember, the frame of reference is at ground level, not the antenna height, so zero degrees is along the infinite flat surface. And there is nothing in there that models where the other antenna is... it just creates a picture of how the strength of the fields are at a given elevation/azimuth angle from the reference point.

Now, in the real world... the ground is never level, even on the ocean where it may look flat it curves down in every direction... so the horizon is not at zero degrees for any antenna above ground level, over flat ground its always below horizontal, on a hill or from a tower its even more negative, and in a valley it can be way above horizontal. both of those cause those predicted patterns to be changed a bit. Also, if the other antenna is not at ground level then it is at some positive angle above horizontal... or if its far enough away maybe a negative angle. You should also note that many broadcast antennas for TV and FM are designed with a tilt to send the signal down toward the ground, especially if they are on high hills or big towers, they would have weak signals near the tower if they didn't tilt it down... of course they don't care about beyond the horizon stuff anyway.

to confuse things even more on vhf/uhf frequencies signals are easily reflected from hills, buildings, and other objects... they are also bent by changes in air temperature and humidity. So in many cases a vhf/uhf signal sent out toward the horizon may get bent down toward the ground and go beyond the horizon by quite a distance, see 'tropospheric ducting' for more info. hf signals of course get refracted back down toward the ground by the ionosphere, so for very distant stations the arrival angle can still be quite high, and almost never straight from the horizon.

See if you can get your money back. I had the same idea a few years
ago and purchased a Safeea Inc MD-2000 tester:
<http://www.allproducts.com/ee/safeea/md-2000.html>
Of course, the first thing I did was rip it apart:
<http://802.11junk.com/jeffl/pics/Microwave%20Leakage%20Detector/index.html>
The diode D1 (labelled C2) is the detector. The apparently random
circuit board traces nearby is the "antenna".

The sensitivity sucks. I'm only able to get an indication when it's a
few cm from the antenna of my access point. Worse, the indication
varies radically from zilch to tilt (9.9mw/cm^2). There's no stable
indication. At the microwave oven leak test distance of 2 inches, it
barely indicates anything, even when I generate continuous traffic
with my iPod Touch. If there were some way to generate a CW carrier
from the access point, perhaps it might deliver a better and more
stable indication.

The problem is that the duty cycle of Wi-Fi transmissions are not
constant. The MD-2000 microwave leak detector works nicely with the
constant duty cycle of the oven controller, but doesn't do as well
with the widely varying duty cycle of Wi-Fi. Also, the duty cycle of
just the beacon transmissions is very low, resulting in a very low
indication.

I also have several analog oven leak detectors, which produce similar
disgusting results.

Topic Drift: Think your microwave oven is well shielded? Put your
2.4GHz cordless phone handset inside the microwave oven. Close the
door. Hit the "page" button on the phone base and see if the phone
rings. It probably will. So much for shielding.

Mine also read close up, but was relatively stable. I was downloading a large
file at the time, so there was plenty of traffic.

Same here, except mine are 1.8gHz.

Geoff.

Is the power specified as pX, pY, or pZ?

What does the 'instrument' indicate? At best it is probably pX, pY, and pZ
on an unmodulated carrier, but none of them on a WiFi signal.

Dave,
Your paragraph above helped. For VHF and above, in the real world, am
I better off using EZNEC's "free space" setting instead of real
ground? I know at HF frequencies, where antennas are often close to
the ground, it makes a big difference, but could free space be a
better approximation of VHF antenna many wavelengths off the ground?

yes, it will probably be a better approximation, especially if the two
antennas are in sight of each other. the ground effect is mostly
appropriate for hf and at very long distance. vhf has many other effects
that cause reflections and ducting that kind of over ride the ground image
model that most modeling programs use.

Hi Pat

I recently re-entered the Ham community after being away from electronics
for 40 years. I was extreemely resistant to accepting the accuracy of
computer modeling. As I have become more familiar with computer modeling
data, I now respect its value very much.
Before acceptance of the accuracy of computer modeling, I recently made my
own complex impedance measurement equipment for 2 meters. I also made
actual radiation pattern measurements using polar orbiting satellites at the
"range illuminator".
Your question about how well the data from EZNEC matches "actual"
radiation pattern is probably related to our not being able to feed the
appropriate information into the computer modeling program.

You are probably interested in 'just learning' how accurate EZNEC is.for
predicting antenna sensitivity toward the horizon when the signal is
horizontally polarized. But, if you want to get actual radiation pattern

data from any given antenna at VHF where polar orbiting satellites are sending a beacon signal, you can simply record the receiver RSSI while the satellite passes overhead.
I have some EZNEC and actual patterns measured using the 137 MHz signals from NOAA satellites. My data wont convince you that EZNEC is quite valuable for predicting the performance of YOUR dipole. But, if you have interest in knowing more about what I have done for recording antenna pattern data using polar orbiting satellites, contact me. I suspect you already know more about what you need than anything I can add.

I ran this with a 15' 9" boom 6m beam at 20 feet over real high accuracy ground, which is at a typical height for a height for a home TV antenna.

The vertically polarized version had a peak of 11.5 dBi at 9 degrees while the horizontal had 16.0 at 13 degrees. At 9 degrees the horizontal still had 15.0 dBi, clearly the winner.

Given that this was very close to the ground in terms of wavelength, it may not be a good example.

Hi Pat,

If you think this experience contradicts EZNEC (or conventional teachings which it concurs with), then the confusion comes from the sense of "very far away." Truly, if you can see the Channel 23 transmitting antenna, then it is not that far away in the scheme of things. It merely points out that you have not correctly modeled your experience.

What is going to be a reflector to a source that is bore-sight with the horizon?

You have, again, lost sight of the meaning of "very far away."

>The EZNEC plot looks more like it is showing additive and subtractive
>combining of the signal.

It is. What you see is called the Fresnel Zone if you were line of sight.

Here, even if you can "see" the Channel 23 transmitting antenna, then its various reflections could add up to ZERO. This, again, confounds expectation, but it is the experience of every mobile operator who encounters "picket fencing."

> I'm not sure what you mean.

My comment was directed to Frank. I'm hoping he'll try running the calculation, or has already. He'll discover that:

1. A horizontally polarized wave does not propagate via a surface wave, and
2. The attenuation of surface waves increases with frequency. At VHF, it's essentially zero at any useful distance.

Either of these is adequate to explain the result he'll see, or has seen, that the result with surface wave is the same as the result without surface wave, for this situation.

Richard and Dave have answered your question -- the reason for the zero field at zero elevation angle EZNEC result is that the model ground is perfectly flat and infinite in extent, and the observation point is essentially at an infinite distance. This is useful for evaluating sky wave propagation at long distances, but not for line-of-sight propagation where Earth curvature can be a factor. Free space analysis is better for this. Programs which calculate reflection coefficients for various ground shapes aren't very useful at VHF and above, because local features, especially in an urban environment, cause reflections that are often much more significant than the ones calculated by the program. All you can do with these programs in a situation like yours is to get a general idea of what's happening.

If by ideal you mean that the ground is perfectly flat and infinite in
extent, yes.

> Richard explained the attenuation of the E-field. That makes sense to

That's exactly what EZNEC is doing. It calculates the sum of two "rays"
-- idealized straight line radiation from the antenna. One is the
"direct ray", which goes directly from the antenna to the observation
point. (Actually, the fields from all segments are individually
calculated and summed.) The second is the "reflected ray", which
reflects from the ground plane to arrive at the same distant point. Some
geometric investigation will show that the reflected ray at an elevation
angle of -x degrees will add to the direct ray at an elevation angle of
+x degrees at the distant point. The reflection coefficient of the
ground, which is determined by the frequency, wave polarization, and
ground conductivity and permittivity, is used to determine the amplitude
and phase of the reflected ray. The reflection coefficient of low angle
horizontally polarized waves is nearly -1 for any reasonable ground
characteristics, so the low angle pattern is nearly the same for a
horizontally polarized antenna over the Earth as for one over a
perfectly conducting ground. If you look the the distance from the
antenna to a distant point via the direct route and compare it to the
distance to the same point via the reflected route, you'll see that the
difference between the two routes (that is, the distances traversed by
the two "rays") monotonically increases with increasing elevation angle.
At zero elevation angle, the two distances are the same. Since the
reflected ray undergoes a phase reversal (as Richard explained),
expressed as a -1 reflection coefficient, the direct and reflected rays
cancel at the distant point, resulting in zero field strength. As the
elevation angle increases, the difference between the two two ray paths
increases, resulting in imperfect cancellation. At some elevation angle,
assuming the antenna is high enough off the ground, the difference in
path lengths will be exactly a half wavelength. At this angle, the two
rays will reinforce at the distant point. At a higher angle, they'll be
exactly one wavelength different, and the rays will cancel again. And so
forth. The path distance difference goes from zero at zero elevation
angle to a maximum straight up of twice the antenna height above ground,
so the number of "flower petals" you see depends on the height, in
wavelengths, of the antenna above ground.

No, it doesn't. Which is why I posted the query to Frank.
>

> Pat, N8CQV

Hope this helps. There's additional information in the _ARRL Antenna Book_ and other sources which explains how the patterns of antennas are affected by ground.

615. 80m/160m trap dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2009-06-21 00:43:05 UTC
From: maxpower <maxpowervk@yahoo.com.au>
Message-ID: <556040d2-41cb-4358-baf5-7f2587b0bfd0@a5g2000pre.googlegroups.com>
Source record: 14477

Hello All,
I have an 80m dipole that I wish to use on 160m as well. I am considering using traps on the existing dipole. I have searched the web and have not found any 80m/160m trap dipoles. Has anyone added traps to their 80m dipole to make it usable on 160m? Or could anyone point me in the right direction towards homebrewing traps to suit. I have made traps in the past for 40m/80m dipoles but I am unsure what dimensions, length, turns etc I would need for homebrewing a trap to make my 80m dipole useable on 80m and 160m.
Thank You.
Cheers
Max

So,EZNEC models "very far away" and, in my example, the channel 23 tower is 5.1 miles away (about 10,000 wavelengths) so I need a different model? A different program? I think you are correct in saying that is my main confusion.

Good example. I started in this hobby 41 years ago on 6 meter AM.
However, I always thought that picket fencing was caused by
reflections from various objects (power lines, airplanes, metal
fences, water towers, etc,etc) rather than the radiation patterns of
the antennas.

That may be true, but I appeciate them trying to help.

Since my last post, I changed the polarization of my EZNEC dipole to
virtical. I expected a nice donut shaped pattern, but instead saw
another flower shaped pattern with deep nulls at various elevations
including zero degrees. When I select free space, I get the donut.

I truely believe EZNEC gives valid results when provided with a proper
model. So, either I am not providing a good model to EZNEC (likely)
or a simple virtical dipole radiates very little at zero degrees
(-90dBi) and a lot at one degree (7.33 dBi), etc, etc (which seems
less likely to me).

>>
>> Frank
>
> Have you tried doing this calculation with a horizontally polarized VHF
> antenna? What did you find?
>
> Roy Lewallen, W7EL
```

As an example I tried the following:

```
CM Horizontal Dipole
CE
GW 1 11 0 0 3 0 1.5 3 0.01
GE 1 -1 0
GN 2 0 0 0 13.0000 0.0050
FR 0 1 0 0 100 1
EX 0 1 6 0 1 0
RP 1 1 360 0000 3 0 1.00000 1.00000 10000
EN
```

At 10,000 meters, 3 meters off the ground:
E(theta) is maximum off the ends at 3.5E-8 V/m
E(phi) is maximum off the sides at 2.6E-7 V/m

This agrees with the expected horizontal polarization off
the sides, and vertical polarization off the ends.

I'll leave the home-brewing to others... its relatively easy, but if
you want to take the simple but more expensive route, there are traps
available commercially... Amateur Radio Electronics carries a fine line
made by Reyco. Their 75 and 80 meter traps sell for $53.00 a pair. I
just sold a pair of 75M traps a few months ago on EHam for $25.00.

The function of a trap is to automatically shorten an antenna for use on higher frequencies. For example, 80 meter traps can be added to a 160 meter dipole to make it usable on 80 meters. But it doesn't work in reverse -- traps won't make your 80 meter dipole work on 160.

You can add loading coils to an 80 meter antenna to make it work after a fashion on 160. But then it won't work on 80 unless you have some way to switch the traps out.

It comes from the "RP" card; line 8 below. I do not know how to
implement this line of code in EZNEC. I am sure there are
plenty of people In this group that know how to do it.

Would a switchable network at the feedpoint work for you? You could
send power to operate a relay up the feedline. The gain/efficiency of
a half length dipole (e.g. 40 m long for use on 160m) isn't all that
bad compared to full size. It's only when you get down in the tenth
of a wavelength or less that you start seeing big changes.

There's probably some standard orientation and test conditions for
these oven leak testers. They're not a "Narda ball" with carefully
designed broadband sensors for all three axes. I'd guess it's
basically a dipole across the end of the business end of the sensor (E
field horizontal, if the meter is laying on the table) with a single
diode and meter. Why do anything more sophisticated.

The shielding in an oven doesn't have to be all that wonderful to meet
the 2mW/cm2 level, either.

For a ballpark, let's say that you've got 1kW spread evenly out on the
inside of the oven. About 30x40x40 cm, or 48,000 cm2. So, in round
numbers 1E6 mW/50E3 cm2 or 20 mW/cm2.. all you need is 10 dB of
attenuation to get down to 2mW/cm2 Obviously, the power density
really isn't even, and you actually worry more about seams, but the
point is that you don't need exotic gaskets and such.

They do make a nifty $100-200 or so WiFi spectrum analyzer which has a
calibrated receiver. And, if you have a wifi card with an exernal
antenna, you can do even better.

If you have the money, a yagi antenna for VHF channels 7 - 13 would be my recommendation for TV. There are also FM yagis. I don't beleive any so-called "All Channel" antenna will peform as well as an antenna intended for a limited band.

UHF TV is tricky and unreliable. About the only thing to recommend it is the high gain antennas tou can build on a smaller boom. In my opinion, VHF 7 - 13 is a better hunting ground.

Could just have been the strong RF in the air. I had something related happen to me. We have a Teddy Bear that sings "We Wish You a Merry Christmas" for 20 seconds whenever you press a button on it. We don't take out the batteries before stowing it overhead in the garage.

In March, I was experimenting with a 40m wire antenna draped over the garage roof. Do I have to tell you what happened whenever I keyed up?
(Eventually, I climbed the ladder and took out the bear's batteries.)

> antenna, you can do even better.

First of all, a $100 item in the US is $200-$300 here (or more, depending upon the regulation required to get it in, the rarity, etc). For example, cheap MP3 players are around 25% more expensive, an iPod is double.

Second, I have never seen a real meaningfull number from a computer. Whether it is MacOS, Linux, or Windows XP, they all give some sort of relative number, for signal strength.

In some cases it has been useful, for example using Kismac, I found that the signal strength as measured by my WiFi card in my Mac, was in the mid 50's with a bluetooth dongle on the computer, and in the 60's without one.

No matter what the number really is 50 is about where it gives up completely.

However, it does not really help me. What I need is to be able to place a device at a specific distance from a 2.4 gHz antenna and read the EIRP.

I can assume that a 100mW signal into the little whip on the back of a router, produces and EIRP of 100mW, which makes all gain antennas illegal. Or I can make an attempt at measuring it. It does not have to be 100% accurate, 10% or even 25% off would be good enough.

For example, I found that placing my meter at about 1 inch from a WiFi router running "full tilt" produced a reading of .36mv/cm2 on the meter. However the only real information I can get from that is yes, the router is transmitting a signal, and yes, I can read it, but no, I have absolutely no clue as to what it means.

I may be asking the impossible, but what I would like to get is a number for example, if I hold the meter an inch from the antenna, 100mW EIRP is 1 mv/cm2. Then I can do something useful with it, as I already know how to compensate for distance. :-)

Hi Pat,

You can use the "near field" table to then build a second antenna (representing your own at the proper distance) with a load, and then look at the power developed to that load to see how things perform. This goes beyond the normal use, but for those who will slog through it, there's a way.

>>Here, even if you can "see" the Channel 23 transmitting antenna, then

>the antennas.

A combination of both, naturally.

>Since my last post, I changed the polarization of my EZNEC dipole to
>virtical. I expected a nice donut shaped pattern, but instead saw
>another flower shaped pattern with deep nulls at various elevations
>including zero degrees. When I select free space, I get the donut.

This is the contribution of ground reflections (which occurs for the horizontal as well).

>I truely believe EZNEC gives valid results when provided with a proper
>model. So, either I am not providing a good model to EZNEC (likely)

It takes discipline to look at the situation without the filter of expectation driving you.

>or a simple virtical dipole radiates very little at zero degrees
>(-90dBi) and a lot at one degree (7.33 dBi), etc, etc (which seems
>less likely to me).

You now enter into the realm of the "Brewster Angle." This is a phenomenon specific to vertical polarization (originally from the field of optics) when an incident ray of radiation meets an interface

and is wholly absorbed by the second media (earth in our case) without any reflection possible, but only for a "critical angle" (another name for this) or less. If you were to change the characteristic of the earth's conductivity (accessible in EZNEC), then you would find you can shift that angle. Selecting a "perfect" ground will present you with a total absence of the Brewster effect, and as high a zero angle response as you might ever want to see.

It is not clear to me whether you are talking about:

1. Increasing the length of your dipole to ~246 feet
and adding 80m traps or

2. "Making your" existing ~123 foot "80m dipole usable
on 160m" by adding 160m loading coils.

Something else to consider is shorting the transmission
line at the tuner and feeding the 80m dipole as a single
wire against ground on 160m where "ground" is ideally a
good radial system.

'traps' are normally meant to cut up a big antenna into smaller pieces for user on higher frequency bands. that is, if you had a 160m dipole you could put 80m traps in it to make the inner part resonant on 80m. to get an 80m dipole to resonate on 160m you need to add loading coils to make it look longer, that will of course make it not resonant on 80m. with some more complex loading and trapping combined you could probably make something that would force it to resonate on 160m and 80m... but its probably easier to just put a tuner at the radio end and got with that.

I have been through some VERY violent storms. I always disconnected all antenna and power leads from the radio. Outside arrestors will help keep it out of the house but you need airspace to protect receiver front ends. Also disconnect any ethernet runs.

Surge protection can only do so much. I learned the hard way about disconnecting stuff. My neighbour across the street had a direct hit and it danced across the phone lines into my equipment. I lost several modems, a couple of ethernet cards and a monitor and considered myself lucky that none of the computers was totalled. But my radios were disconnected and unscathed.

Now the coast station I worked for had a direct hit on our Nautel 500khz transmitter's tower. Blew out half the solid state final modules but the damn thing kept right on ticking on the others!

641. Can you ID this antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2009-06-22 12:11:09 UTC
From: Gary KW4Z <gkendric@gmail.com>
Message-ID: <0826ec54-8e88-4b30-a12a-f849889eefd3@l8g2000vbp.googlegroups.com>
Source record: 14403

The other day, while passing the local Reserves building, I noticed a new antenna mounted to their tower. It was in an inverted Vee form but had approximately three white insulators that were around 6 to 8 inches in length running between the two wires of this antenna. The antenna was fed, via coax, from the bottom by what appeared to be a balun. The wire proceeded out from the balun past the bottom of the three (per side) insulators and at each end appeared to either double back, upon itself, or be attached to the top wire which was connected to the bottom wire at each end then passed through the top of each of the three (per side) insulators and ended up meeting the other sides, top wire, at, what appeared to be, a plastic mounting plate that served as a fastening point for each of the top wires and also as a top support for the antenna's middle to be connected via rope, wire, etc to either a tower or mast. The top (middle) of the antenna had no contact with the bottom middle (of the antenna), where it was fed from, but the top and bottom wires (isolated from each other as it ran from the middle to end, by three white insulators approx 6-8 inches in length) The only contact of the top wire to the bottom wire was at the extreme ends of this inverted vee type antenna where the top and bottom wires were attached to each other then each end mounted, via insulator, to some connecting point to support the height of the ends of this antenna.

I've just never seen this type antenna and would love to build one. If you know the type, from the description I have given, please share the name of it and where I might be able to obtain the forumulas for calculating length. What bands does it work? Is it homebrew or commercial?

Any input would be appreciated.

Sounds very much like B&W's "folded dipole". I use quotes because in their
version they have a resistor at the center of the unfed wire that absorbs
power and smooths out the VSWR.

>>> MUST ground the shields that's OK and you can use lightning arrestors
>>> on both coaxes.

This is probably not going to work in most cases. Remember an open wire
feedline can have
rather high voltages on it compared to a matched coax liine. This is
because they are often
mismatched at the antenna.
If a voltage peak should happen to occur at the place where you have the
arrestor, it can fire
the gas tube because of the rf voltage.
For example, a gas tube arrestor made for legal limit typically has a firing
voltage of about 800 volts. In a matched
50 ohm system, even with a full 1500 watts into 50 ohms the peak rf voltage
is in the neighborhood of
600 volts. But even a moderate power into a high impedance open line could
be enough to fire
the gas tubes. Neither the transmitter nor the gas tube would be happy with
this situation.

The NASA Global Differential GPS System.
"The NASA Global Differential GPS (GDGPS) System is a complete, highly accurate, and extremely robust real-time GPS monitoring and augmentation system.
"Employing a large ground network of real-time reference receivers, innovative network architecture, and award-winning real-time data processing software, the GDGPS System provides decimeter (10 cm) positioning accuracy and sub-nanosecond time transfer accuracy anywhere in the world, on the ground, in the air, and in space, independent of local infrastructure."
http://www.gdgps.net/

This would be enough for the positional accuracy at this wavelength. This type of highly accurate receiver would probably have to be used only by the installers as they are likely to be expensive. Perhaps the positional accuracy could be maintained over time by referring to a satellite signal.
The "time transfer" accuracy mentioned apparently does mean the many different sites can be put in time synchrony to within sub-nanosecond precision by reference to the atomic clocks on several GPS satellites at the same time:

http://www.gpsworld.com/gpsworld/Innovation-GPS-Time-Transfer/ArticleStandard/Article/detail/383189

However, JPL radio astronomer Dr. Dayton Jones responded to my question about the required timing accuracy at such long wavelengths, suggesting it might only have to be only at the ten's of nanoseconds to even microseconds range, depending on the bandwidth being detected:

Newsgroups: rec.radio.amateur.space, rec.radio.amateur.antenna, sci.astro, sci.astro.seti, sci.space.policy
From: rgcl...@my-deja.com (Robert Clark)
Date: 18 Jun 2001 10:26:50 -0700
Subject: Re: Will amateur radio astronomers be the first to directly detect extrasolar planets?
http://groups.google.com/group/sci.astro.seti/msg/8a56d6bc52a09590

Note that with the Radio JOVE system the bandwidth being detected is usually quite small at the tens to hundreds of khz range, as the emissions consist of short pulses. This would only require timing

accuracy at the microsecond range.
For the cost, note that for cable, DSL, satellite, internet and/or TV service typically the receivers, modems, routers, etc are only "rented" where you pay a nominal fee every month. If the cost for the dipole and receivers were in the range of $100 dollars per installation then this could be amortized over the life of that broadband internet system, at say $1 dollar a month or even 50 cents a month.

Ok.. so the Wi-Spy is going to be a bit on the pricey side for you.

>
> Second, I have never seen a real meaningfull number from a computer. Whether it

What software are you using to get the signal strength from the WiFi
card? AND, is your WiFi interface one that actually supports scanning
and measuring signal strengths (not all do.. it's less and less common)

However, if you have a card that supports it, you can probably get a
quantitative (but not necessarily calibrated) measurement.

That's not a valid assumption. You'd have to look at the FCC
registration data for the device (assuming the configuration is the same
in the US as you have) and see what their analysis is. Gain antennas
aren't necessarily a problem, even under Part 15.

> Or I can
> make an attempt at measuring it. It does not have to be 100%
accurate, 10% or even 25% off would be good enough.

Your problem is going to be finding a way to calibrate your measurement.
Do you have ANY calibrated signal source around? If so, you can build
a standard gain antenna, and generate a known field to measure with your
measurement device.

>

I assume you mean 0.36 mW/cm2... That's probably an average power (with
the averaging done by the meter movement).

>
> I may be asking the impossible, but what I would like to get is a number

> to compensate for distance. :-)

If you hold the meter an inch from the antenna, the meter is going to
alter the performance of the antenna.

You need something with some gain (or better sensitivity), so you can
put the probe farther away (e.g. more than a meter), and still make your
measurement. If your device under test is radiating 100 mW, the
surface area of a 1 meter radius sphere is about 130,000 cm^2, so 8E-4
mW/cm2. (call it -30dBm/cm^2) At 2.4 GHz, a wavelength is 12.5cm, so
a dipole will be half that, or 6cm. The effective aperture will be
around 10-20cm^2 (I can't remember off hand), so a receiver hooked to a
dipole probe needs to measure -20dBm sorts of power levels, which isn't
too bad. There's a bunch of inexpensive power detector ICs around that
have sensitivities spanning this (like the AD 8314.. goes -45dBm to
0dBm, 2.7GHz, $1 each in quantity)

You could probably get a sample or two for free. Build a tiny board that
combines the AD log detector and some sort of display or IR telemetry
and a small battery, with the dipole sticking out.

You got that right (about the expensive receiver). More to the point is that getting survey grade measurements requires having the antenna and receiver in place for a long time. You also need to have GPS antennas that are well characterized for the purpose (phase center vs look angle) and that deal well with multipath and such (i.e. you've probably seen guys with the choke ring antennas out doing GPS surveys). There's also a fair amount of technique. There's a reason the survey grade GPS costs >$10K and the guys and gals who use it get paid what they do. (you might want to look up the SCIGN Southern California Integrated Geodetic Network.. they're doing basically what you're talking about.

Yes, it is possible, with <$500 equipment, scrounging, and much amateur toil, to get this kind of performance, but not on a regular basis. If you have a good quality receiver with the right outputs (say you have an old Motorola OnCore or one of the newer ones) and some time and effort, you could probably measure the motion of your house as the plates move.

> The "time transfer" accuracy mentioned apparently does mean the many

Yes. This is pretty standard stuff. But not cheap or easy. Getting to
10-20ns is straightforward, getting to <1ns is not. There's a whole
raft of factors that conspire against you, and they're all in the few ns
range.

If all you're doing is timing pulses AT ONE STATION, sure. If you're
trying to combine MULTIPLE signals coherently (which is what you're
doing), you need MUCH better performance.

Someone has to pay the capital cost. The cable company is happy to rent
it to you, because they make money on the monthly fees, some of which
goes to pay for the borrowed money for the cable boxes.

I don't see cable companies investing any money in this (where's their
revenue stream?)

Dale,

Though not exactly like the B&W antenna that you linked to it is similar enough that I feel it has to be based upon that antenna design. Jimmie, I'm sorry I totally lost you in the description. I'll see if I can get a photo however all of you are aware of the security precautions since Sept 11. My apology if the description was not concise enough to enable you to identify.

That's true. You would probably need air-gap arrestors that can be
adjusted to not arc on normal transmitted voltages.

Still, the only really effective way of feeding a non-trap wire system on
several bands that I've encountered is to use open wire.

This one was built by a friend (without my involvement). I rather like the use of common hardware store parts and pieces. I'm trying to convince him to make some changes and to replace the electrical wire elements with sheet aluminum, but otherwise, methinks it's rather clever. I haven't made any measurements yet, so I don't know how well it's matched.

>80m. with some more complex loading and trapping combined you could
>probably make something that would force it to resonate on 160m and
>80m... but its probably easier to just put a tuner at the radio end and
>got with that.

If you already have an 80m halfwave dipole, you will need to add your
80m traps at the ends. Anything added beyond the traps will 'not be
seen' on 80m.

You will then need to extend the dipole beyond the traps, adding
sufficient wire to make it resonant on 160m.

If there were no traps, the additional length of wire needed would be
around 67'. However, below their 80m parallel resonance, the 'effective
inductance' of 80m traps will act as loading coils, and the length of
wire needed will be less than 67'. [Note: The effective inductance will
be greater than the physical inductance of the coil itself.]

How long (or 'short') the additional wire will need to be will depend on
the L/C ratio of the traps. A large L/C will require less additional
wire). You might get away with (say) 30'. If you can't accommodate this
amount of wire, you could always cheat by winding some of it,

effectively as another loading coil.

Note that, because your 160m dipole has inductive loading (from the 80m traps alone, plus any additional loading you have to add), it will have less bandwidth than a full-size 160m dipole.

Of course, an easier alternative approach might be simply to use an open wire feeder, and a tuner in the shack. The existing 80m dipole will be reasonably efficient on 160m as it is, but it could be improved by extending the existing dipole (assuming you have the space available).

Thank You all for the replies.
Ian, what you haved written is what I am trying to do. I have an 80m dipole up at the moment that needs to be relocated.
I thought I might as well put it up where I could put some 80m traps inline and extend it for 160m. I haven't got enough room for a half wave 160m dipole, but I could possibly squeeze in an 80/160m trapped dipole, depending on how much extra length (with the 80m traps) I need to add to get it to resonate on 160m. I have since found a drawing for a 40/80/160m trapped dipole. I will make up the 80m traps from that plan, add it to my 80m dipole and see how I go.
Cheers
Max

The B&W, which comes in several configuations, is a pretty standard military antenna. We had several of them on various buildings at Ft. Meade, where I worked and I've seen them on military posts all over. Several other commands at Ft. Meade also had them. I've also seen then at some local reserve armories as I drive by them.

With an antenna tuner (usually automatic) they can cover the whole HF spectrum.

As it is a government issue, it likely can be made by several vendors to government specs and then bid upon, unless there is something so unique about it that it is a sole source contract. Some of them I inventoried when doing site inventories (I was a US Dept. of Defense program manager) were, in fact sold to the gov't by B&W which I believe is short for Barker & Williamson who made ham transmitters in the 1950's when I was both a kid and first licensed.

I'm not an antenna engineer by any means but someone who was said that essentially is was a sort of hybrid between a Zepp and a folded dipole. The extra spacing contributed to its bandwidth. He said the center had some sort of insulator with a balun transformer. It was not the most effecient antenna, but could be erected quickly and was packaged with a mast kit for field operations.
The military version also had the option of stainless steel wire.
Most of the ones I saw were permanently installed.

I was always curious about them, but all my projects were receive-only for intercept so I never got to play with them at all.

Like to hear more about them.

Good for you ! You're building your own. For planning purposes, I would comment that with my purchased Reyco 75M traps I had to add about 40 feet of wire beyond each trap for resonance around 1900KHz... but of course this will vary depending on the inductance of YOUR home made traps. If, during your design process your traps are built with more inductance vs capacitance, you might be able to shorten the 160M portions less than mine were. Good luck.

Dunno. I haven't had time to play with it or bug the builder (name
withheld). He just sent me the photos and asked me for advice on some
details. I don't like the "phasing" lines between bowties. I would
say it's NOT ready for prime time, yet. He's now building a huge
version of the same antenna.

If you wanna build your own, look into construction articles on
Gray-Hoverman antennas such as:
<http://www.digitalhome.ca/ota/superantenna/>
<http://www.casano.com/projects/hoverman/index.html>
<http://www.engadgethd.com/2008/04/06/diy-gray-hoverman-antenna-promises-better-ota-recept
ion/>
etc...

Remember... the uglier the antenna, the better it works.

One of the best "air-gap arrestors" of the home-brew variety I have seen,
was made with a couple of Wide Gapped Spark-Plugs, threaded into a 1/4
Steel Plate that was bonded to a very deep Grounding System. The fellow
used GTO15000 to connect the spark-plugs to the Wire-Feeders. Worked
very well.......

It was probably one of these:

http://www.bwantennas.com/

Works on a wide range of HF frequencies, popular with the government,
but a tad expensive (upwards of $1,595.00 is a lot for a dipole) and
you lose a certain amount of power in the antenna.

I had comcast news for several years until they dropped newgroups a year
ago. So I switched to motzeralla.org which recently changed all its news
servers to "eternal-september.org"
http://www.eternal-september.org/
They are free but your download total is limited in several ways, but I've
never bumped into the limits. They do not support the binaries at all.
Otherwise it works just fine for me.

Also, you will need a e-mail account that is not AT&T or Bellsouth, as for
some reason, AT&T/Bellsouth has blacklisted eternal-september.org. A
hotmail or yahoo account works just fine. (used for account verification).

666. HR 2160 - restrictive covenants webinar Thursday

Newsgroup: rec.radio.amateur.antenna
Date: 2009-06-24 12:36:08 UTC
From: ARRL MW Division <memberlist@www.arrl.org>
Message-ID: <20090624122405.22AC2301B8@www.arrl.org>
Source record: 14428
Cross-posted to: rec.radio.amateur.moderated,rec.radio.amateur.antenna,rec.radio.info

Midwest Division members,

Hams have been happy to have the tools available in PRB-1 to combat restrictive municipal government ordinances against antennas and towers. We have wished for these protections to be extended to private covenants, which PRB-1 did not speak to. In many urban areas it's virtually impossible to find a home not subject to private restrictive covenants.

Now HR 2160 has been introduced into the US House of Representatives. In a two-step process this bill might well give us PRB-1 type ammunition to use when trying to erect amateur antennas in covenant communities.

Thanks to the division members who have already written their congressional representative in support of this bill. For more background check out
http://www.arrl.org/news/stories/2009/05/12/10818

Atlantic Division Director Bill Edgar has sent the following invitation. If you have interest in facilitating protection from restrictive covenants this webinar will be of interest. Please consider attending. And have a rewarding Field Day. -:- k0bj -:-

The Atlantic Division is sponsoring a webinar about HR 2160 for our members on Thursday, June 25th at 8:00pm EDT. We have space for 1,000 people to listen and view this presentation.

Dave Sumner was gracious enough to offer his help in doing this presentation.

You are welcome to invite your division members to join in with us. There is no cost for attendees to listen/view this presentation. You are also invited to register as well to attend.

Participants must register in order to listen/view the presentation and all they need to do to register is to click on the URL:
https://www1.gotomeeting.com/register/596535705

They're found on the roof tops os US Embassy's as well. If the design
incorporates a resistor there will be additional loss, but that is the
trade off when you need a multiband antenna that plays well with ALE.

We were issued dipoles which had to be retuned with each frequency
change through out the day. Sometimes efficiency isn't everything.

They're found on the roof tops os US Embassy's as well. If the design
incorporates a resistor there will be additional loss, but that is the
trade off when you need a multiband antenna that plays well with ALE.

We were issued dipoles which had to be retuned with each frequency
change through out the day. Sometimes efficiency isn't everything.

How much power did the military use with that type of antenna? I used to
mess around at the Delaware armory communication setup (MARS?) back about

twenty years ago, but I don't remember the power levels they were running.
Hi, Tom!!!

Ed Cregger, NM2K
(I got my old callsign back after having AJ4PJ - I couldn't take being away from it)

Do a Google on "T2FD", and you will find lots of information on this antenna. I believe the Cebik did an analysis of it, but his articles are not as accessible as they used to be.

guessing a large and fast ammount of lightning induced current
traveld along the ckt trace it got hot and fried creating the
open voltage no longer could pass and so never reached the
other parts ie chips etc

so prob by luck you had enough current to damage the trace dosn't
take much, but not enough to arc over and contine damage

673. OCF Dipole and Window Line Choke

Newsgroup: rec.radio.amateur.antenna

I'm going to 450 ohm window line to my OCF Dipole. Obviously, as confirmed by EZNEC, without some kind of choking action at the feedpoint, my feedline will be radiating. What kind of 1:1 choke could I use on the 450 ohm line at the antenna feedpoint? I could build a 1:1 choke with the right toroid but not sure if I can maintain the 450 ohm line Z0 through the choke.

It is very difficult to choke 450 ohm window line.
I would suggest a husky 1:1 current-choke-balun at
your window-line/coax junction. The Carolina Windom
advertises feedline radiation as a benefit/feature.

With an OCF, fighting feedline radiation is usually a
losing battle.

No, you cannot, but is that important? Select a product that works
and connect the line to it, and the antenna to the other side. Of
course "works" means: offers sufficient Z in relation to the load and
the line. "Sufficient" means: 10 times Z.

Going further, what is the point of 450 Ohm (sic) Window line in this
application anyway? An OCF would only demand a 200 - 300 Ohm line
depending on where the off-center is off center.

Given there are an infinite off centers to every center, that makes
for a lot variation in drive point Z. Have you selected the optimum,
or just going for an ad hoc design? Given your 450 Ohm desire for an
antenna reputed to be 200 Ohms, it would seem you are guessing.

As you report you have EZNEC, the solution is at hand. Put up the
longest wire you can run. Place the source at the center of 101
segments. Set the alternative SWR source Z to 100 Ohms. Run a full
sweep from 3 to 30 MHz at 10 kHz increments. On a separate chart of
about 10 columns, make notes of each dip in SWR (about 4) in columns
that are spaced equal to the dip's relation to the full 3-30 sweep.
Now move the source 5% and repeat the steps. Keep moving the source
towards the end by 5% steps, again repeating the steps.

I've done this and know where the "best" offset is, but telling would
cheat you of your investment in EZNEC.

I'd let the feedline radiate. It's a part of the package.

Also, is there a reason that you wouldn't use coax instead of window line? Your impedance on amateur frequencies should be such that a 4:1 or 6:1 balun at the (off) center point then a run of coax should work well.

There can be substantial radiation from an OCF dipole feedline even with an effective choke in place. The asymmetrical positioning of the feedline relative to the antenna results in a net induced common mode current, while a choke only stops the current at one point. Effective reduction of induced current can require two chokes placed about a quarter wavelength apart, which isn't practical for a multi-band antenna. In practice, you might have to fiddle with the feedline length (since some lengths will result in more current than others on particular bands) in addition to using two or more chokes in order to drop the feedline radiation to a tolerable level. I think that with an OCF dipole you've just about got to expect some feedline radiation.

Hi Mike

I modeled a 4:1 at the feedpoint in EZNEC. I would need 100 feet of 50 ohm line. Loss on RG-58 at 3.7 Mhz is 3.25 db. At 28.3 Mhz loss is 4.7db. Those are "best swr" frequencies for those bands. Operation on either side of them results in even greater loss. Similar results on other bands. RG-8 cuts the losses in half but the variation in SWR I mentioned makes that a still unacceptable option for me. No amplifier here so conservation of power delivered to the antenna is important to me.

Thanks Roy. You've pretty much confirmed what everyone else is saying regarding feedline radiation. Hadn't thought about the induced contributor from the asymmetrical configuration. So a 90 degree feedline takeoff in this situation would still result in induced current it would appear. I added a wire simulating the radiating feedline conductor in my EZNEC model. It appears from the FF patterns it may be helping in some directions.

While I've got you, is there any way in EZNEC to add an RF ground counterpoise at the source end of my model? I have a long wire at my common equipment ground point to better enable RF grounding on my equipment and would like to see if EZNEC can tell me anything about its effectiveness. I can't figure out how to tie the wire in to only the ground side of a source. I read up on split sources but still can't be sure I'm doing this correctly.

You're right Richard. I am working with an "ad-hoc" design. I'll try
your method, but since I've only got 450 ohm line to work with, other
than lossy coax, I'll use 450 as the alternate Z0.

Yes, that's correct. And sometimes a single common mode choke (current balun) can actually make it worse by forcing near-zero current at a point favorable to the current distribution.

> I added a wire simulating the radiating
> feedline conductor in my EZNEC model. It appears from the FF patterns
> it may be helping in some directions.

It may well be. But in order to really know what the common mode current will be, you'll need to accurately model the entire path to the Earth, because that path (length and orientation) determines the common mode current distribution.

The way to do it is to put your (conventional, non-split) source on the end segment of the counterpoise wire, and connect the transmission line end to the same segment, rather than using a virtual segment for the interconnection.

Ok Roy I added the RF ground counterpoise as you stated above, but it
would appear to me all I did was add another antenna wire at the
source end of my model. I did ground one end of the RF ground
counterpoise, but I'm having a tough time seeing how the source is not
just seeing this as another antenna wire. Maybe that's the way it
should be, but in the physical world the counterpoise is only
connected to transmitter ground and my transmitter is not trying to
drive it through the center conductor.

I differ with some of the other advice that you have.

I suggest that the "appropriate" common mode impedance is independent of differential Zo. I refer to this as Rule 500, as it usually requires the magnitude of common mode impedance to be 500 ohms or greater for use on a 50 ohm line.

Rule 500 is born out of a lumped circuit analysis, and is less relevant to the antenna scenario with its coupled conductors. Like most Rules of Thumb, it is spruiked without stating or often knowing the underlying assumptions and is then RoT.

You could create a model of your antenna, including the common mode current path and insert the common mode impedance as a load in the relevant conductor in the model, and explore the effect with different choke impedances and frequencies etc.

My article at http://www.vk1od.net/balun/W2DU/index.htm shows that done, in that case with a W2DU balun. Several other articles on the site model the common mode impedance of ferrite cored baluns, so they might give you some ball park figures to try (eg http://www.vk1od.net/balun/Guanella/G.1-1.htm).

The model also allows you to explore the importance of a shunt path to ground outside the shack as an element of mitigating common mode current.

You may also come to the conclusion that Rule 500 is not applicable to the scenario.

Sorry, I don't understand. EZNEC has no idea of what you consider to be an "antenna", "counterpoise", or "ground" (except when connected to a perfect or MININEC-type ground plane). A conductor is a conductor, just as in the real world. It sounds to me like the model matches your setup -- the terminal of the source connected to the long wire is the transmitter "ground", and the other source terminal is the transmitter "hot". But if the suggestion I made doesn't match the physical configuration of your setup, then it needs to be modified so it does. Unless other readers are interested, contact me by email and try again at describing the physical setup if you still need help with it.

It can certainly be done. The hardest part for me was figuring a way
to lock the thing in at the top. Wound up using a spring loaded bar
that slid into a corresponding 'loop' on the hazer. The rest is just
simple and not so simple mechanics, sort of. You might think about
putting 'rub' buffers on the hazer, some kind of plastic or whatever.
Good luck.

Welcome to the world of RF. On a long "ground" wire,
the only place that is at "ground" is where it is
grounded and at 1/2WL intervals. With standing waves
on that wire, there are points at which the impedance
(and voltage) is sky high - yes, on the "ground" wire.

Pick ones with the right materials and loose tolerances (so it doesn't
rust and the inevitable crud doesn't jam it)

OR... high density polyethylene (poor man's Teflon).. cutting boards are
a good source.. quite durable, easy to cut to make rub pads or rings or
forks.

Thanks for the reply Cecil. I am aware of the physics of RF on
longwires. What I am having trouble with is how to include a longwire
RF energy sink at the source end of my antenna model. These are
normally 1/4 wavelength at the operating frequency (or band midpoint
for a best fit) and are open circuit on the far end resulting in a low
impedance path for stray rf energy as part of the station ground
configuration. Look back at Roy's reply on how to implement this in a
model. The way he suggested would appear to have the source driving
the 1/4 wave ground wire as an end fed element. Just doesn't look
right to me. The source should only see this wire on the ground side
of the model.

There are any number of alternatives, each matching the situation of
"someone." They vary by rather simple to rather elaborate estimations
of "ground." At least one can be found in the generous help manual.

The trick is how well you know your "ground's" characteristic to
sufficient accuracy. Chances are you (given you have an ad hoc
design) you barely know. This, of course, translates into a model of
equal imprecision.

Myself, I lay out several dozen radials over an average earth and
connect to it. If it is a simple dipole, I lay out a ground mat below
the antenna (it does make a difference).

Ive only seen one DIY hazer. It was a larger tower section slipped over the regular tower and the guy had added some rollers and guides. This might be a real pain to install if the tower is already populated with antennas. This was a show and tell at a club meeting and lets see its been 15 years since I went to a club meeting.

Anyway his biggest point was that it was pretty easy to make once you knew how to make the guides, just take a section of tower that will slide over yours and bolt on the guides. Of course there's the matter of the winch and pulley system. I didnt catch that part.

Dave K4JRB,

I ran into a weird problem with our new HDTV. Anytime I would transmit with over 100 watts the RF was QRMing the remote control receiver inside the Sony and causing the Menu to flash on and off. No issues at all with audio or video. The fix was the addition of common mode filters.

Check out the article on page 40 of the July issue of QST for pictures and more details.

704. High data rate space transmissions through visible light communication.

Newsgroup: rec.radio.amateur.antenna
Date: 2009-06-28 06:54:14 UTC
From: Robert Clark <rgregoryclark@yahoo.com>
Message-ID: <d93b5c96-717b-43b1-8178-eec713504a89@h18g2000yqj.googlegroups.com>
Source record: 14516
Cross-posted to: sci.astro,rec.radio.amateur.space,rec.radio.amateur.antenna,sci.astro.seti,sci.physics

I had been thinking about methods of high data rate transmission in regards to getting *video* transmissions from Mars orbiter missions. I was irritated by the spotty coverage of the Mars surface at the best resolutions so I wanted to send real-time *continuous* imaging back to Earth receiving stations at the highest imaging resolutions. This would require very high transmission rates, much higher than what is currently used.

The idea would be to use light transmissions but only of the on-off variety. You would use a large surface, many meters across, capable of being alternatively lit up and darkened. There are computer chips of course capable of operating at Ghz rates. This would determine if the large surface was lit up or not electrically, possibly by using a material whose reflective properties can be changed electrically.

I was worried though about the twinkling seen in point sources, which this would appear to be, such as with stars due to atmospheric effects. So this might require the telescope(s) to be in Earth orbit. The question I had though was whether the atmospheric distortion would cause an "on" signal to appear "off" and vice versa? My understanding of atmospheric distortion is that it causes the point source to be constantly apparently undergoing small shifts in position. But this wouldn't be a problem if what you want to determine is whether it is on or off. If that is the case then ground based telescopes would work.

In the large reflecting surface, I actually wanted to use separate, say, squares on the reflecting surface that could be put separately in the on-off position to increase the information transmission rate. But that would require being able to distinguish the squares from Earth millions of kilometers away. This is why I wanted to use light rather than radio for this since the larger wavelengths in radio would make the reflecting surface impractically large for diffraction limited resolution.

Even with light you couldn't do this with a single telescope. They would have to be widely separated. Combining the signals from widely separated scopes is common in radio astronomy but is not nearly as successful in optical astronomy. That is because the light wavelengths are so much smaller and you would have to have nanoscale accuracy in positioning the widely separate mirrors in relationship to each other. However, in the case of just detecting an on-off signal this shouldn't be as big of a problem as you're not trying to form a usable image, but only trying to see if a particular location is on or off. You would need though highly accurate timing synchrony between the separate scopes, within nanoseconds, to be sure they are detecting the same on-off square. Note also here that the shifting in the image due

to atmospheric distortion very definitely would be bad for using
ground based scopes.

It occurred to me this might be a means of acquiring advertising
support for a Google Lunar X Prize entrant. I had also been trying to
come up with a method of having an illuminated image either on the
Moon or in lunar orbit that would be visible to the naked eye on
Earth. Such an idea was discussed here:

moon advertising.
put a billboard on the moon.
http://www.halfbakery.com/idea/moon_20advertising

I wouldn't be in favor of doing this in a way that would actually
advertise a product. But I was thinking about it as a way of sending a
message in favor of, for example, world peace. In this case you could
still have advertisers who could say in TV commercials for example
they supplied funding to support the mission and the message.
BTW, I would be in favor of advertisers who could pay to have
advertising signs set up at the rover landing site so that if anyone
who wanted to log on to the the rover transmissions or who watched a
TV program on the rover transmissions would see the ads. This to me is
something different than an ad that someone would be forced to see
just by looking up at the Moon.
In any case you would need something large enough so that with naked
eye resolution at the lunar distance it would still be
distinguishable. This page gives the naked eye resolution at the lunar
distance:

Purpose of Building Telescopes.
http://www.astronomy.org/astronomy-survival/telepur.htm

According to this page the resolution of the human eye at the lunar
distance would be about 22 miles. One single object clearly couldn't
do this. However, if you had separate illuminated landers or orbiters
at this large distance apart they could be used to send a message
visible to the naked eye on Earth.
It could work with orbiters by the example set of satellite formation
flying by the Cluster mission:

Cluster mission.
http://en.wikipedia.org/wiki/Cluster_mission

I also needed to find how large a brightly illuminated surface needed
to be at the lunar surface to be visible by the naked eye on Earth. I
thought of the example of the "Iridium flares":

Satellite flare.
http://en.wikipedia.org/wiki/Satellite_flare

The Iridium satellites have 3 antennas that happen to be also
reflective in visible light, totaling 4.8 m^2 in area. According to
the Wikipedia page, the flares can be up to -8 in apparent magnitude,

though typically at +6 magnitude, and are produced by an individual antenna, so by one of area 1.6 m^2.
I'll assume the brightest flares are produced just by the orientation the antennas happen to be in so we could make our reflective surfaces be oriented with respect to the Sun to get the greatest brightness.
For the same size surface, the brightness would be lessened by the greater distance to the Moon. The Iridium satellites are at about 780 km altitude so the Moon is about 500 times further. This would lower the brightness by a factor of 500^2 = 250,000.
This page gives the apparent brightness commonly visible by the naked eye in urban areas as +3:

Apparent magnitude.
http://en.wikipedia.org/wiki/Apparent_magnitude

The 250,000 times lesser brightness at the lunar distance for an Iridium sized reflective surface would give it a +13.5 higher apparent magnitude so up to +5.5 in apparent magnitude. To make our reflective surface be at +3 apparent magnitude we could make the area be 10 times larger, so at 16 m^2 area, or a square 4 meters across.
We would need a method for a flat reflecting surface of unfolding it to this size. It might be easier instead to have the reflecting surface be a balloon inflated by stored gas. Since this would be in a vacuum, you wouldn't need much gas pressure or mass to accomplish this.
Another consideration is that because of the brightness of the Moon it could swamp out our illuminated surface. For the orbiter, this could probably be alleviated by having the orbiter have a highly elliptical orbit, (this also would be beneficial in minimizing the required delta-v and fuel load) then it would be visible at the higher distances from the Moon in its orbit. For the landers it might work for them to land in the dark lunar maria.

To communicate the message though we would need a method to turn on and off the reflecting surface. One possibility would be to have the reflecting surface consist of very many small squares that could be rotated to reflect toward the Earth or away. Another possibility might be to have it covered with LCD's. Whichever method it would have to be both lightweight and low power.
For our first attempts we probably would not want to send so many orbiter or landers at once to form a naked-eye visible image. We would first send just a single one to test it out. Note that this method with a single vehicle could still be used to send high definition video by having our single reflective surface be turned on and off at the required rate, about 256,000 times per sec with compression.

Nice idea, but ...

Illuminating an area of Mars or the moon and relying on this secondary reflection will actually produce less photons returning to earth than aiming the light source directly at the earth.

Furthermore, the radiation from a reflected area is isotropic - goes in all directions - and hence very little is directed towards the earth.

If you were using the light source directly, rather than having it illuminate an area of the ground, you could also use lenses or mirrors to focus it back on the earth, giving thousands or millions of times the signal strength on earth, the same technique as is used for radio comms.

"Robert Clark" <rgregoryclark@yahoo.com> wrote in message news:d93b5c96-717b-43b1-8178-eec713504a89@h18g2000yqj.googlegroups.com...

than radio for this since the larger wavelengths in radio would make the reflecting surface impractically large for diffraction limited resolution.
Even with light you couldn't do this with a single telescope. They would have to be widely separated. Combining the signals from widely separated scopes is common in radio astronomy but is not nearly as successful in optical astronomy. That is because the light wavelengths are so much smaller and you would have to have nanoscale accuracy in positioning the widely separate mirrors in relationship to each other. However, in the case of just detecting an on-off signal this shouldn't be as big of a problem as you're not trying to form a usable image, but only trying to see if a particular location is on or off. You would need though highly accurate timing synchrony between the separate scopes, within nanoseconds, to be sure they are detecting the same on-off square. Note also here that the shifting in the image due to atmospheric distortion very definitely would be bad for using ground based scopes.

It occurred to me this might be a means of acquiring advertising support for a Google Lunar X Prize entrant. I had also been trying to come up with a method of having an illuminated image either on the Moon or in lunar orbit that would be visible to the naked eye on Earth. Such an idea was discussed here:

moon advertising.
put a billboard on the moon.
http://www.halfbakery.com/idea/moon_20advertising

I wouldn't be in favor of doing this in a way that would actually advertise a product. But I was thinking about it as a way of sending a message in favor of, for example, world peace. In this case you could still have advertisers who could say in TV commercials for example they supplied funding to support the mission and the message.
BTW, I would be in favor of advertisers who could pay to have advertising signs set up at the rover landing site so that if anyone who wanted to log on to the the rover transmissions or who watched a TV program on the rover transmissions would see the ads. This to me is something different than an ad that someone would be forced to see just by looking up at the Moon.
In any case you would need something large enough so that with naked eye resolution at the lunar distance it would still be distinguishable. This page gives the naked eye resolution at the lunar distance:

Purpose of Building Telescopes.
http://www.astronomy.org/astronomy-survival/telepur.htm

According to this page the resolution of the human eye at the lunar distance would be about 22 miles. One single object clearly couldn't do this. However, if you had separate illuminated landers or orbiters at this large distance apart they could be used to send a message visible to the naked eye on Earth.

It could work with orbiters by the example set of satellite formation flying by the Cluster mission:

Cluster mission.
http://en.wikipedia.org/wiki/Cluster_mission

I also needed to find how large a brightly illuminated surface needed to be at the lunar surface to be visible by the naked eye on Earth. I thought of the example of the "Iridium flares":

Satellite flare.
http://en.wikipedia.org/wiki/Satellite_flare

The Iridium satellites have 3 antennas that happen to be also reflective in visible light, totaling 4.8 m^2 in area. According to the Wikipedia page, the flares can be up to -8 in apparent magnitude, though typically at +6 magnitude, and are produced by an individual antenna, so by one of area 1.6 m^2.
I'll assume the brightest flares are produced just by the orientation the antennas happen to be in so we could make our reflective surfaces be oriented with respect to the Sun to get the greatest brightness. For the same size surface, the brightness would be lessened by the greater distance to the Moon. The Iridium satellites are at about 780 km altitude so the Moon is about 500 times further. This would lower the brightness by a factor of 500^2 = 250,000.
This page gives the apparent brightness commonly visible by the naked eye in urban areas as +3:

Apparent magnitude.
http://en.wikipedia.org/wiki/Apparent_magnitude

The 250,000 times lesser brightness at the lunar distance for an Iridium sized reflective surface would give it a +13.5 higher apparent magnitude so up to +5.5 in apparent magnitude. To make our reflective surface be at +3 apparent magnitude we could make the area be 10 times larger, so at 16 m^2 area, or a square 4 meters across.
We would need a method for a flat reflecting surface of unfolding it to this size. It might be easier instead to have the reflecting surface be a balloon inflated by stored gas. Since this would be in a vacuum, you wouldn't need much gas pressure or mass to accomplish this.
Another consideration is that because of the brightness of the Moon it could swamp out our illuminated surface. For the orbiter, this could probably be alleviated by having the orbiter have a highly elliptical orbit, (this also would be beneficial in minimizing the required delta-v and fuel load) then it would be visible at the higher distances from the Moon in its orbit. For the landers it might work for them to land in the dark lunar maria.

To communicate the message though we would need a method to turn on and off the reflecting surface. One possibility would be to have the reflecting surface consist of very many small squares that could be

rotated to reflect toward the Earth or away. Another possibility might
be to have it covered with LCD's. Whichever method it would have to be
both lightweight and low power.
For our first attempts we probably would not want to send so many
orbiter or landers at once to form a naked-eye visible image. We would
first send just a single one to test it out. Note that this method
with a single vehicle could still be used to send high definition
video by having our single reflective surface be turned on and off at
the required rate, about 256,000 times per sec with compression.

I have been thinking along these lines in a slightly different way. I choose to call the traveling part a "tram". I have a forty foot utility pole ready to plant but there is no way I will ever climb it. It is a little more complicated because it is about 12 inches in diameter at the bottom and about 6 inches in diameter at the top.

I envision something like an inverted crank up tower mechanism. I am planning a long sleeve (3 feet?) pulled up by one or two steel cables. As the tram approaches the top, vee notches in the upper end of the sleeve will engage a big pin through the pole to align & stabilize the horizontal position. The vertical positioning will be accomplished by wedges length wise on the pole that do not engage the inner surface of the tram until the last few feet of travel.

There is no new technology here so no patent issues. The choice of materials for the tram is important, it must be strong but light as possible!

If anyone is inclined to turn my idea into a commercial product I would be flattered!

Actually, it is lambertian in its distribution, and it would have a
major lobe that was directed in rather typical fashion (at the same,
but negative angle to the norm to the surface). However, as is the
intent of your response, very much less will find its way to the
intended target.

A curious distinction in this "continuous." Direct Current
transmission from Mars? I think not. Anything else is rather
conventional.

>This
>would require very high transmission rates, much higher than what is
>currently used.

"Continuous" is not distinctive to rate except at DC. Grab both sides
of conventional 120VAC from any wall socket, and it will seem
distinctly continuous - boosting it 1 THz wouldn't bring any different
sensation.

>The idea would be to use light transmissions but only of the on-off
>variety.

Rates, and on-off have departed the realm of "continuous."

>You would use a large surface, many meters across, capable of
>being alternatively lit up and darkened.

This is entirely unrelated to "continuous" rates or modes of
transmission. In and of itself, in regards to establishing remote
communications at light wavelengths, it is guilding the lily and
painting the rose.

>There are computer chips of
>course capable of operating at Ghz rates.
How that relates to:
>This would determine if the
>large surface was lit up or not electrically, possibly by using a
>material whose reflective properties can be changed electrically.
is bordering on stream-of-consciousness rambling.

>I actually wanted to use separate,
>say, squares on the reflecting surface that could be put separately in
>the on-off position to increase the information transmission rate.

There is no causal correlation between many surfaces and rate. This
is merely the substitution of complexity for the appearance of deep
consideration (which it is not).

>This is why I wanted to use light rather
>than radio for this since the larger wavelengths in radio would make
>the reflecting surface impractically large for diffraction limited

You are simply limited in your perception of what RF and Light means.
If one suffers for wavelength, then they both do.

>Even with light you couldn't do this with a single telescope.

Sounds like an artificial objection. Have you tried thinking in terms
of a power budget?

>They would have to be widely separated.
Does not come naturally as a solution from the rather diaphonous
problem put forward to this point, and the following is not a reason:
>Combining the signals from widely
>separated scopes is common in radio astronomy but is not nearly as
>successful in optical astronomy. That is because the light wavelengths
>are so much smaller and you would have to have nanoscale accuracy in
>positioning the widely separate mirrors in relationship to each other.
This is problem of degree, one which you painted yourself into a
corner with. Further, it doesn't necessarily follow one from the
other.

>However, in the case of just detecting an on-off signal this shouldn't
>be as big of a problem as you're not trying to form a usable image,

>ground based scopes.

This is, based on your own objections, rather whipsawed by the
application of the term "nano." Nanoseconds and nanometers are not on
the balance to the solution of your problem. If you had nanometer
issues optically, they are not solved within nanoseconds simply
because they are not forming an image (which is a poor metaphor
because if fails with its own application).

>moon advertising.
>put a billboard on the moon.
>http://www.halfbakery.com/idea/moon_20advertising

Half backed? It is undercooked by half that again.

Let's consider: To obtain a sufficient contrast ratio, the light
would have to exceed the brilliance of the sun.

Did I mention a power budget?

The rest of this hardly borders on novely so much as fantasy. Keep
that to the appropriate groups.

Yes, you are perfectly dead on the spot for using the visual spectrum
on behalf of interplanetary and interstellar communications, as by far
the most extremely narrow of monochromatic or those of FM photons
accomplishing their one-way or ideally two-way energy and technology
efficient alternative. I kid you not.

The problem is that it’s perhaps too darn good and perhaps even too
energy efficient. Signal pointing and tracking errors from a
satellite platform are seriously narrow, though receiving isn’t all
that insurmountable.

I had a look at your model and couldn't make head and tail of it.

Here is a simple model of a Carolina Windom, well to the extent that it can be guessed from the smoke and mirrors used to describe and promote it... http://www.vk1od.net/files/CW01.EZ .

The model attempts to represent a voltage balun at the dipole feed point, a vertical coax feedline to a common mode choke (2000+j2000) and then the coax outer is grounded via a moderately good station ground (directly under the feedpoint). The power lost in the ground connection and the choke can be found from the reports. The model does not attempt to represent the differential mode transmission line, though it could be done. The CW's voltage balun at the feedpoint is modelled as a pair of equal voltage sources, with the common mode path connected between them. I have treated the voltage balun as having zero common mode impedance, it is probably a few ohms, but insignificant in this model.

As Roy I think already advised you, you have to model the entire common mode path to ground and my example above is a simple one, but it demonstrates a technique.

You will see the currents flowing in the three conductors (each side of the dipole and the coax outer), and their contribution to / effect on the pattern.

Others may disagree with my representation of the Carolina Windom.

Owen

This describes the reflection from the Iridium antennas as specular
where most of the reflected light is concentrated in a single
direction:

SeeSat-L Apr-98: Method for predicting flare.
http://satobs.org/seesat/Apr-1998/0175.html

About specular reflection:

Specular reflection.
http://en.wikipedia.org/wiki/Specular_reflection

We could get even higher concentration of the image by using
parabolic mirror reflectors.

On Jun 28, 4:51 pm, Owen Duffy <n...@no.where> wrote:

> I had a look at your model and couldn't make head and tail of it.

Owen, maybe the following description will help with understanding my model.

The antenna is an OCF Dipole in a Vee configuration. Wires 1 and 3 are the short and long sides respectively. Wire 4 is just a short connector at the apex. The antenna is fed with 100 feet of 450 ohm line which transitions through a 4:1 transformer to 5 feet of 50 ohm coax and then to the source. Wire 6 is an attempt to simulate the unbalance radiation from the 450 ohm line. Wire 7 is an approximate 80m 1/4 wave RF "sink" on the ground side of the source end of the model and is not meant to be a main element radiator so its position relative to the other elements is immaterial.

Also, as you can see, I have wire 6 grounded which isn't actually the case in the physical world. It is meant to simulate radiation from the 450 ohm line which actually ties into the 200 ohm (ungrounded high Z side) of the transformer. I guess I figured grounding it was the right thing to do since the EZNEC Help file implies the need for that to simulate coax radiation. I do have wire 6 positioned correctly relative to the other antenna elements, so its effect on the antenna pattern should be accurate.

Don't let short wire 5 which looks out of position throw you. It just serves as a termination junction between the 50 ohm side of the transformer and the short run of coax. There are a couple of other short "junction only" wires in the model.

A look at the wires, transmission lines, transformers, and sources tables should aid in understanding the model.

I by no means mean to imply I've modeled everything correctly. I just wanted you to know what I was attempting when I built the model.

Thanks for the Carolina Windom model. Good reference for comparing to what I have done.

Also, thanks for looking at this. Any advice much appreciated.

Yes, and it was all doable as of more than a decade ago. However, at
the rate we're going, perhaps another century is required.

You have two parts to your model, and they are disconnected (apart from conductor coupling effects). You have complicated your model with your counterpoise concept and it doesn't work.

Try a simple model with not more elements than necessary, then when you have it working, current look rational etc, extend the model.

Hint: the TL element models the differential mode of the transmission line, and NOT the common mode. To answer your original question, you do not need to model differential mode TL, just put the source(s) up in the centre of the dipole.

You do need to know the common mode impedance of your 4:1 transformer to include it in the model. If it is a voltage balun, you can probably treat it as zero ohms without introducing great error, but if it is a current balun (as your mention of choke implies), you need to know its impedance at the model frequency.

Bob,
You might not want to cross-post to 5 groups.

1) what spotty coverage? I doubt any gaps are due to the lack of data bandwidth from Mars to Earth, except when MRO goes behind Mars, or similar line of sight interruptions. There's a non-zero cost to running DSN antennas, too. In any case, getting sufficient bandwidth in a pipe to earth isn't a matter of technology, it's a matter of money.
2) Optical comm with very high bandwidths is a subject of research and development at NASA (at JPL) and the USAF (at Lincoln Labs). Lots of interesting ideas for receivers on the Earth, etc. Doesn't take a huge telescope or high powers at either end. They use, IIRC, a form of pulse position modulation.

There was a special issue of IEEE Proceedings October 2007 (Special issue on Technical Advances in Deep-Space Communications and Tracking) that discusses a lot of this stuff. (including optical) Read it and learn, rather than just looking at press releases and formulating ideas from that.

I'm not an amateur radio guy or anything like that. I recently bought a Kaito KA1103 Worldband Radio, mainly to get better reception of AM stations. I sometimes like to listen to discussion shows at night and the local selection is limited. The reviews seemed to indicate that the radio has good AM discrimination, etc. Well, so far it doesn't seem to be any better than my little 20 year old Sony Walkman radio. I've also scanned through the short wave frequencies and found nothing, but that was not my main reason for getting the radio.

The radio came with an "antenna" that seems to be one big loop of wire with a plug at one end that goes into the radio and a plastic clip at the other end. I'm not sure what to do with it and have read somewhat contradictory advice on the internet. Nothing that I have tried has resulted in any better reception. I also see somewhat inexpensive loop antennas advertised.

Any suggestions for improving AM reception would be greatly appreciated.

Thanks.

First, the external antenna is intended for shortwave, so that's not
going to help.

The reviews I read stated that AM was quite good, better than some
radios that I know are good, but that the AC adapter is quite noisy. If
you are using that, try running just on batteries.

If that doesn't work out for you, locate a GE Superradio or go C Crane
site and get a CC Radio. The CC Radio is the best I've ever used that
has straight AM detection and costs less than $300. Their site is
www.ccrane.com.

good luck

Hi "Ted"

If you wanted AM stations in the 0.5 to 2 MHz band, you might be happy
with a tuned loop. I went "overboard and made a big multiturn loop that can
be located outside but tuned and rotated from inside, It gets too
complicated to both rotate and tune a big, outside AM Loop antenna. But,
that really works well for reception of AM radio from long distances. You
might find something in this site http://www.mindspring.com/~loop_antenna/

Here what you ight consider doing;
The additional wire should, hopefully, increase the signal you capture.
If you have window close to where you listen to your radio, stretch the
wire around the room , at the highest level you can INDOORS. I use cup
hooks to supend the wire. This will improve the shortwave signals. To
improve the MW signals in the AM band, do some researach at some of the
Yahoo groups on MW natennas and it has much more infor mation than I
can list here. The 1103 is good portable, but DO NOT hook it up to an
outside atenna. It will overload and you will get false signals
everywhere. A good loop antenna or a Select-Tenna will improve the MW
section. Hope this helps. Email me if you have questions. KE5LDO.

> appreciated.

Medium-wave AM reception can be difficult in an indoor environment due to shielding provided by nearby wires and especially from the steel frame of a building. Radio noise from light dimmers, touch lamps etc nearby (yours and/or your neighbors) can limit AM reception, also.

This Kaito radio has a built-in ferrite antenna that is used for AM broadcast reception. It is directional with best reception when the longest dimension of the radio is perpendicular to the direction to the station it is receiving. The telescopic whip is used for short wave and FM broadcast reception, only.

According to the Operation Manual at
http://www.ccrane.com/instruction-manuals/kaito-ka1103-radio.pdf
, this radio needs a field strength as high as 1 mV/m on the AM broadcast band. That is rather high, but some of the 50,000 watt AM stations like WJR (760), WLW (700), KMOX (1120) etc can produce nighttime fields that high or higher over wide areas of the US.

The "Local/DX" switch probably should be in the DX position when listening to distant stations, unless you are located close to an AM station with a very strong signal at your location (experiment).

You might take your radio outside to see if reception improves. If it does you may need to use an external MW antenna such a "long wire" or the C. Crane unit at
http://www.ccrane.com/antennas/am-antennas/twin-coil-ferrite-am-antenna.aspx
. Unfortunately, the Crane antenna costs more than you paid for your Kaito radio, probably.

LOFAR.
http://en.wikipedia.org/wiki/LOFAR

LOFAR like my proposal is to use many separate dipoles to detect long wavelength radio waves. However, it is to have only 10,000 dipoles whereas mine at the end will have ca. 1 billion dipoles.

The progenitors of the LOFAR project have argued in papers that it could be used for the SETI search. However, this article by well known SETI search scientist Seth Shostak argues LOFAR will be too weak to detect Earth type radio transmissions at a distance of say 55 light-years by a factor of 1 million:

Listening for ET’s Television.
November 9, 2006
by Seth Shostak, Senior Astronomer
http://www.seti.org/Page.aspx?pid=917

Then since my proposal will be about 100,000 times more sensitive than LOFAR, it could detect Earth-like radio transmissions to about 1/3 the distance of 55 lightyears, or to about 18 lightyears way. There are several star systems in that range. The Shostak article notes you could get several hundred times better sensitivity by listening to certain stars over months or years. Then my proposal could detect such transmissions out to even 55 lightyears and further.

Sorry to hear that. Mine is running strong at about 10 years old.

Never played with a Yacht Boy. My experience with Grundigs is with the smaller/cheaper models which aren't impressive and the giant ones that are way too expensive for the performance they give. The big ones aren't bad, but not close to the performance of what I could buy a used amateur rig for the same price, so I've stayed away.

The display in my original CCRadio failed, too -- I sent it back to
the Crane folks and they put in a new display for $25, one that has
much better longevity, they say. Still going strong after several
years.

I have employed a certain technique with success. It takes a longwire antenna, preferably strung high and clear. Bring the free end of the wire into the house and wrap it around the radio about a dozen times and then ground the end. You have wound a crude RF transformer. If you have hum or buzzing, you may be able to cure it by repositioning the longwire.

You might not know how the rod antenna is mounted inside the case; experiment to get the optimum improvement. In a radio with a big case, you can locate the antenna rod with any remote control. Simply hold the remote control at different places around the radio and press a button. Where the remote makes the most noise, that's where the rod is. You can test a remote for dead/alive this way, too.

I have also opened up a radio, wound a small coil (again, just a few turns) around the antenna rod and brought the two ends out of the radio, grounding one and connecting the other to the longwire antenna in para 1.

Properly employed, this absolutely works.

When I was in the Navy on a ship in Pearl Harbor, my longwire antenna was the telephone wiring for the ship. I got a few clicks and pops from dialing pulses, but I also got to listen to AM radio in my bunk. A small cap isolated the phone's DC. On another ship, I had a single piece of hookup wire that ran out on deck through a convenient door near my berthing compartment and I wrapped it around some piping on deck. I was questioned about it a few times, but I got to keep it. (It's good to be the Chief.)

Best ever was my office desk on the aircraft carrier Oriskany. I snaked a coax cable up near the top of the island structure to the antenna patch panel of the meteorologists. I shared their 35' whip through an SRA-12 band-splitting filter. (They never used the BCB outputs, anyway.) I bummed my very own patch cord from the radiomen, coded it with yellow tape and asked the meteorologists if they minded that I added a patch cord to their patch panel. They didn't. (It's good to be the Chief.)

With the weather-guessers' whip, I got KNX-1070, Los Angeles between Hawaii and Guam, about 3700 miles. (Wish I'd sent them a reception report but I didn't; I called the bridge and got our LAT/LONG.)

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.

Even easier is using a flat piece of plastic sheet (from an old bleach bottle or something similar) perhaps 1" x 3 or 4". Wind it full of hookup wire held in place by duct tape. One end of the winding to ground and the other to an end fed wire antenna which is highly unlikely to be a longwire. Tune in a distant Medium Wave signal with the built-in antenna then begin moving the new winding about on the back of the radio's case until the signal peaks up. Either tape it in place or use a couple of pieces of Velcro to attach it to the back of the receiver.

Hi,

I like to listen to ham radio HF bands and short wave broadcasts, but
I often have intermittent power line noise. I found a source (power pole,
possibly bad insulator), but when the person from the power company came out
to investigate my complaint, the noise wasn't there (intermittent).

Running a wire antenna perpendicular (not parallel) to power lines is one
way to lower power line noise, but unfortunately, the power lines run North to
South where I live. My wire antenna also runs North to South so it "favors"
East and West, which is what I want.

Can anyone recommend a noise immune type of antenna that is less
sensitive to power line noise?

Thanks in advance, Brad

Before you type your password, credit card number, etc.,
be sure there is no active keystroke logger (spyware) in your PC.

Not necessarily. At my previous QTH, the power line
noise was mostly vertically polarized coming from
a 30 foot ground wire running down from a capacitor.

You might get some relief by grounding the antenna for DC. Since you are not using the wire for transmitting (am I reading the above correctly?), you can easily ground the wire using an RF choke or a so-called magnetic balun. Perhaps a 1 mH or so choke from the end of the wire to ground. The balun is basically just a toroid transformer that allows you to isolate the wire from the radio and ground the wire directly.

No guarantee of effectiveness, but either is easy and cheap to do and won't harm the radio.

Since your noise seems to be primarily coming from this single noisy source, you might consider buying one of those noise cancellers such as the MFJ-1026 and learn how to use it. They do work well under such circumstances as you describe.

Better, though, to persist with the power company until they can take care of the problem.

Hi, Brad.
My previous home was adjacent to a primary power distribution line
with three high voltage three phase lines, plus a residential
distribution line. Sometimes noise was fierce. I made a folded dipole
antenna out of 300 ohm TV twin lead, cut for the 75 meter ham band.
When first hooked to a receiver, I thought the receiver had died, but
eventually found a signal and it was working fine. Just no more noise
from the power lines.

If you can find a length of twin lead, try a folded dipole. I
currently use a horizontal loop antenna and it, too, is very low noise
pickup.

Before I discovered the T2FD, the noise was soo bad that I never pursued my ticket. The T2FD's balanced nature reduced local QRM from S9 to S1.

Some people here will tell you all the problems with this type of antenna but I've had great fun over the last 4 years. I constructed mine from plans off the web but you can purchase these already to fly.

Out of the blue, I just received this email from C.Crane Co.

"I read online that you have a display problem with your CCRadio. Upon looking into your account I can see it is a CCRadio Plus which is far easier to put our newer display technology into than an original CCRadio. In fact we can do this at no charge. We would only need you to send the radio to us. We take care of shipping the radio back to you. John Wilder, Customer/Product Support, C. Crane Company, Inc."

WOW!

Now that's customer support.

I am officially impressed.

tom

Hi Paul,

Thank you for that information.

Also, thanks to everyone.

I found information on the T2FD antenna that was also recommended.

Brad

On Thu, 2 Jul 2009 11:21:43 -0700 (PDT), in rec.radio.amateur.antenna you wrote:

751. fiberglass Sat boom?

Newsgroup: rec.radio.amateur.antenna
Date: 2009-07-05 01:58:31 UTC
From: ml <m@di.net>
Message-ID: <m-FE13DA.21583104072009@news.optonline.net>
Source record: 14363

hi

Wanted to see what people thing regarding the design of a modest satelite set up hopfully soon to be installed.

I was going to get the Yaesu as/el rotator and a circular pol beam by M2 both for 2m and 430. at a future point i might put a small 1296 ant on it as well.

the 2m/430 beam antennas are around 10ft and mount in the middle.

I have sorta two options for the EL boom.

a) i can use a fiberglass mast

question, how strong are these I was also looking at the M2 one in particular

anyone know of anything better ?

b) how much of a difference signal wise would it make going from the fiberglass to say a regular metal boom (EL)??

C) any special advantage that might be afforded due to the less weight?

thanks and happy 4th

753. Obtaining electromagnetic radiation from accelerating electrons

Newsgroup: rec.radio.amateur.antenna
Date: 2009-07-05 12:24:20 UTC
From: Richard <nearlynews_email@ntlworld.com>
Message-ID: <7bbkckF22jlreU1@mid.individual.net>
Source record: 14365

Is it not true that if I were able to accelerate my cup of coffee at light speeds at a frequency of 14Mhz my cup of coffee would radiate a 14Mhz carrier?

754. Re: Obtaining electromagnetic radiation from accelerating electrons

No.
You don't have to go the speed of light . Bigger the acceleration,
bigger the amplitude of the radiated signal.

And, it's the vibrating your cup of coffee back and forth at 14MHz
that would do it.

Another problem.. there's no net charge on your coffee.. so no
radiated field when you move it back and forth.

Consider a balloon which you've charged up by rubbing it on your hair
(or that fuzzy sweater...) If you move it back and forth, and have an
electric field meter some small distance away, you'll see the field
changing. Move the meter farther away, and the field is still
changing, but the amplitude is smaller.

Now look at the time delay between your moving the balloon and when
you see the field change. That delay is the time it takes for the
changed field to "propagate" to the meter.. aka the speed of light.

How many free electrons in coffee? How about salt water?

757. FS Drake MN-2700 Antenna Tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2009-07-05 22:18:26 UTC
From: Charlie Hugg <k5mbx@sbcglobal.net>
Message-ID: <SE94m.3467$bq1.577@nlpi066.nbdc.sbc.com>
Source record: 14369

FS: Drake MN-2700 Antenna Tuner capable of handling 2000 watts PEP. It covers all ham bands from 160 to 10 meters, including the WARC bands. It has a very accurate built-in SWR and Power Meter. It works great. This is an early production unit and has the gummy paint on the cabinet. The cabinet is in good condition, but would look better if stripped and repainted. The front panel is excellent. I am the second owner of this antenna tuner. This unit comes with the original Drake Instruction Manual and the original letter from Drake to the customer and the Quality Control Record Tag with the Serial Number of the unit and the date Oct 29, 1979. Price is $285 plus shipping. Thanks, Charlie Hugg, K5MBX

I lived in Chicago in 1962-63 and DX'ed channel 2 in Miami at 5:30 A.M.
in the winter. Sometimes it pays off and sometimes not. That was back in
the days of test signals, many with the Indian, and I took snapshots of
the screen with my camera. No VCR's back then either.

I never did that well. Late night Buffalo NY received in Norfolk VA was my best (1969). The picture was good enough a bunch of us sat around and watched the movie!

Norfolk was an interesting location -- just a few local stations in those days, so it was good for DX. I was at sea level, but I had a 50-foot mast and no surrounding obstacles.

Channel 5 was funny. With the antenna aimed approx northeast, we got Channel 5 from Washington DC. Then, without changing the channel, we rotated CCW and got Channel 5 in Washington again, but it was Washington, NC, a completely different station.

Sal

If the cup was to move 5 meters left, then 10 meters right, then ten meter
left again that would be one cylcle. There are 14 million cycles in one
second. So, net speed of cup is speed of light.

Actually the frequency ought to be 15 Mhz.

765. rotator side brackets?

Newsgroup: rec.radio.amateur.antenna
Date: 2009-07-06 11:25:06 UTC
From: ml <m@di.net>
Message-ID: <m-CC55F4.07250606072009@news.optonline.net>
Source record: 14377

hi

wondering if anyone knows a place i can get a set of brackets that
will allow a rotator to be mounted to an existing tubular mast.

I won't have a tower, just a mast, remember seeing someplace that
sold a set of brackets that allowed the rotator to site off on the
side on a bracket/shelf and another that held a thrust bearing

so from afar it looked like a mast then another mast to its side

anyone know any company(s) that make these??

thanks

> Actually the frequency ought to be 15 Mhz.

Nonetheless, you still have acceleration, speed, and frequency seriously
confused. If you want to do a "thought experiment" (or any experiment,
for that matter), you must formulate it properly if you want to draw
sound conclusions from it.

And the "clarification" about frequency also makes no sense.

Either the cup has infinite acceleration at each end of its motion, or it
accelerates steadily from zero speed to a maximum at the middle and then
decelerates to zero again. The first implies an infinite change in
momentum and kinetic energy. The second implies a speed higher than the
speed of light at the middle of the motion.

You can't postulate conditions that defy the laws of physics and then ask
what physics implies anyway.
```

This is all WAY off topic, so we should end it.

I used a piece of PVC pipe with a wooden closet pole inside it. It is holding up a KLM 22C and the 435 KLM antennas. The 435 antenna is mounted at the back so the coax comes out the back side and does not get in the antenna patern. I did not go out the back of the 22C 2 meter antenna, but ran it up the boom and out the side. I did turn the antenna so the elements are at a 45 deg angle to the boom so the coax is halfway between the elements. I do not know if that makes any differance or not. I did work Oscar 10 and 13 while they were at the maximum distance running 100 watts on 435 into about 75 feet of the 9913 type coax on both antennas.

If you do not go out the back of the antennas with the coax, I doubt it would make much differance what kind of cross boom is used, especially on two meters if the coax is taped to the cross boom.

I have not used the antennas in a while , but think all the sats are now in a low earth orbit and it should not take too much to work them anyway.

768. 2 baluns on doublet feedline to overcome impedance changes?

Newsgroup: rec.radio.amateur.antenna
Date: 2009-07-06 14:28:33 UTC
From: "bugzilla.97@googlemail.com" <bugzilla.97@googlemail.com>
Message-ID: <e40fe68c-7d4d-4afe-a215-f784dd0d621b@g1g2000yqh.googlegroups.com>
Source record: 14380

hi, everybody;

i am interested in constructing a choke balun for balancing a doublet
75 metres long, centre-fed with 30 metres of ladder line, an l-match
between the rig and the feeder;

i have read around a bit, including roy lewallen's splendid article
below; it seems that a balun maintains balance best when its inductive
reactance outweighs the line impedance by a factor of at least 4;

at about 2 mhz, the impedance at the bottom of my feeder will be high,
resulting in considerable imbalance on the line (more so that the
frequency is low, where the balun's inductive reactance is lower); i
have two questions;

1) would a balun at the antenna end of the line (where the impedance
is much lower) maintain balance in both antenna and line?
2) and then how about another balun at the l-match end of the line,
for frequencies where the antenna-end impedance is high?

your assistance would be appreciated; best wishes

The antenna is balanced. The feedline is balanced. What you
would need is a BALBAL, not a Balun. I haven't seen any
BALBALs advertised lately.

> 2) and then how about another balun at the l-match end of the line,
> for frequencies where the antenna-end impedance is high?

When I ran into the same problem, I decided to adjust my
ladder-line length per band so the balun would always be
looking into an impedance between 35 ohms and 85 ohms.

pH = -log hydrogen ion concentration

the pH is about 7, so hydrogen ion concentration is 1E-7. It's
neutral, so there's an equal number of negative ions. How many of them
are free electrons is another question.

But the important thing is that there's an equal number of positive and
negative charges floating around there, so there's zero net charge. An
possible radiated field from a negatively charged electron will be
exactly matched by the opposite field from a positively charged
something else.

one thing i neglected to mention is that the rig is grounded;
according to the roy lewallen document i referred to, the ground
connection causes imbalance, regardless of the ladder line;

another clarification; my lower-case typing back there caused a
counter-intuitive reproduction of the phrase `L-match'; the match
between the feeder and the rig is an L-match; it does not isolate the
ladder line from earth

Hi All,

With a small TV antenna from Sears (like Sal, back in the mid 60s), up
5 feet above the roof (split level), on the crest of a hill (6200 feet
in Colorado Springs), I was able to DX Calgary and Edmonton.

The pH of water in contact with the atmosphere tends to be about 6.5, due to CO2 dissolving in the water and forming carbonic acid. Other commonly-occurring ions that "match" the H+ are sulfate and nitrate. Of course in salt water, most of the ions are sodium (Na+) and chloride (Cl-). Not many free electrons. The motion of any ions could create electromagnetic radiation, but as you note, the net charge is zero, so no radiation, regardless how the cup is accelerated or what speed it travels at ;-)

Does that mean a column of salt water could not be
used as an antenna?

A grounded rig doesn't necessarily cause imbalance
in balanced systems. For instance, a primary/secondary
isolated transformer will cancel the common-mode
components at the transformer secondary windings.
(Such a transformer works best when optimized for
a single band.)

> i'm also aware of the link-coupled transmatch;

Unfortunately, the secondary winding in the Johnson
Matchbox is referenced to ground through the loading
capacitors. It appears the Johnson designers didn't
consider common-mode problems.

It just means that moving the water back and forth won't cause
radiation. Waves on the surface of the ocean don't make radio signals.
(C'mon, Cecil. You knew the answer to your question, didn't you? ;-))

The column of water will conduct a current, which will radiate, but I
think I'd rather use copper or aluminum :-)

Unless you can stuff that antenna into a container the size
of two shoe-boxes, and achieve a 9 point something dBi
gain on 160M at the same time, yeah, you're wasting time.
Art's already beat you to it. And Art's antenna doesn't
care one never-mind about the phase information in the
standing wave current ;>) good luck in the contest.

The impedance seen between the two line conductors isn't what determines how well a balun works. What's important is that the common mode impedance of the balun is at least several times (ideally ten or more times) the common mode impedance seen at the balun insertion point. The latter isn't easy to determine. If the balun has adequate impedance relative to the common mode impedance, it will maintain balance at that point. Basically, if you put the balun at a point where the common mode current is high (which is a point of low common mode impedance), it'll reduce the common mode current at that point to a low value. If there's no substantial current due to mutual coupling (due, for example, to a non-symmetrically placed feedline), this will balance the entire system. If you put it at a point where the common mode current is low, it won't change things much.

If there's common mode current due to coupling, putting a balun at one point will change the current distribution but not necessarily balance the whole system; you can still have common mode current on the feedline but with a different distribution. When that happens, two baluns placed about a quarter wavelength apart will usually disrupt all possible distributions and result in good balance.

But the points of maximum and minimum common mode current will be different for each band, and will depend on the length of the feedline and the total path to the Earth. So there's no single solution that's best for all circumstances. You're usually stuck with trying various combinations until a satisfactory solution is found.

> 2) and then how about another balun at the l-match end of the line,
> for frequencies where the antenna-end impedance is high?

What this will do is assure that you don't have a significant amount of common mode current at the rig, which is a good thing. Putting one at the antenna assures that the antenna legs have equal and opposite currents, which is another good thing. What happens between depends, as I described above, on a number of factors.

If a VEE antenna were formed of two hoses, these "elements" could be
partially filled with brine and tuned by draining or adding brine. The
metal fittings on the lower ends of the VEE elements would be the feedpoint.

Reductio ad absurdum

LXXIII,
Sal

786. Seeking New FAQ/Intro Maintainers for rec.radio.amateur.*

Newsgroup: rec.radio.amateur.antenna
Date: 2009-07-07 06:05:01 UTC
From: rram@panix.com
Message-ID: <radio/ham-radio/recruitment-1-1246946700@panix.com>
Source record: 14398
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.amateur.policy,rec.radio.info

```
Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/recruitment
Revision: 1.1 2007/09/29 18:42:47
Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.
```

been done, been patented too, I think.

(conductive liquid as a changeable antenna element)

Miami was my best ever. Sometimes I could get WCCO in Minneapolis, Grand
Rapids, Michigan, and a few stations from Iowa. I had the biggest
antenna you could buy with a CDR (real) rotator and a nuvistor amp at
the antenna. Plus a 30' mast on top of the house. A bit over the top for
a 13 year old but it kept me out of trouble and drove my parents nuts to
have the TV turned on at 5:00 A.M. When that was not giving me signals I
went to my room and fired up the Hallicrafters S-108 with a 200' antenna
out to the fence in the back yard. Not ideal but I got the whole world
at one point or another.
I was not your average 13 year old, more like a prototype geek.

In California we would call that hill a mountain. DX'ing here is only north and south since I am in the central valley north of Sacramento, but I did sometimes get Reno, Nevada. It only worked up to channel 5 and then 6 and 7 were somewhere higher, then 8 to 13 were too high for any DX'ing stuff. UHF barely even existed back then unless you got a converter box, which I did not.

Now I am back to my Hammarlund HQ-129 and an RME DB-20 tuned pre-amp.
The Hammarlund barely needs it but it does help some for getting C.B. on
the top.

Depending on where you are in Colorado Springs, you could be at 6200 feet without being on a hill at all, and it probably wasn't any more than 200 feet high since the lowest point in town is more than 6000 feet above sea level. The propagation wouldn't be any better than on top of that size hill anywhere else. Here in Oregon, a 200 footer is barely a "hill", and certainly not a "mountain".

So if 200 feet is a "mountain" in California, what do you call Whitney and Shasta, and the Sierra?

Roy Lewallen, W7EL
-- who used to live in a valley at 5200 feet above sea level. . .

795. Twin lead versous Ladder LIne:

Hello to all
Going to build a Mystery Antenna to take to the lake for 2 weeks
http://www.w5gi.com/mysteryantenna.htm
It says to use 300 or 450 ohm window line.What I am asking if there is a real big diff if I use 300 Twin Lead.
I realize that the power handling capacity is reduced,but I will be only running a max of 100w for a short duty cycle(not a big talker).
And I also realize that it is not mechanically as strong.Has anyone have some thoughts on this.
I will be using a manual tuner on this type of antenna.
Thanks to all in advance
Howard

TV-type twin lead will in general have markedly worse characteristics
when there's water on the line. 100W won't be a problem until moisture
soaks in.

There are several different types of ham window line with different
gauge conductors and solid vs stranded. Copper-plated-steel window
line like sold by Wireman and others has a handy property: it
remembers that it was originally coiled which can help with stowing it
for portable/occasional use. Handle it wrong and it'll wrap around you
like a cobra :-).

True ladder line (all empty space except for spacer rods) will be
superior to either twinlead or window line.

Any antenna beats no antenna, so don't fret the details too much in an
effort to perfectly clone someone else's setup. Just getting any wire
into the air and loading up into it ought to be the first goal, not
making the pefect clone of someone else's mystery antenna.

Tim.

Hi Bill,

No, in Colorado, mountains don't really begin before 8-9,000 feet
(with 100 peaks above 10,000 feet). Last year I was driving through
passes at 11,000 feet.

6200 feet in the Springs is basically out on the prairie on a slight
rise. The antenna thus was only 20 odd feet above average ground, and
that average ground was a slight hill of 300 - 400 feet. I had a
clear view of the front range and Denver's TV antennas were on that 60
to 80 miles north-north-west - probably just line of sight through the
Black Forest given the marginal signal. Denver, the Mile High City,
actually sits in a bowl. The generally lowest point in Colorado (if I
am not mistaken) is out on the SE corner at about 3500 feet where it
is definitely in the great plains (as you would have been for hours
driving to get there).

>DX'ing here is only
>north and south since I am in the central valley north of Sacramento,
>but I did sometimes get Reno, Nevada. It only worked up to channel 5 and
>then 6 and 7 were somewhere higher, then 8 to 13 were too high for any
>DX'ing stuff. UHF barely even existed back then unless you got a
>converter box, which I did not.

The TVDX was during the summer, late afternoon, on the low VHF and
lasted 20 minutes up to 90 minutes - I got to see a full movie out of
Edmonton. On other occasions I would get a long, slow flutter that I
convinced myself was from a freight train tracking along the distant
skyline. Even though the antenna was pointed towards Denver, the
Canadian cities were not particularly at the peak of the lobe.

At one time, I lived within a mile of the blast doors of NORAD in
Cheyenne Mountain. Back then they kept a free fire zone in front of
it - what with the Red Scare and all. Now the slopes are littered
with suburb ranch style homes. I guess many of those occupants are
not Heinlein fans of his "The Moon is a Harsh Mistress." My chemistry
teacher used to cheer us up by saying the Ruskies would probably send
enough missiles to turn Colorado Springs into a plain of glass if

things got bad.

798. Looking for Cushcraft Antenna Repair Kit

Newsgroup: rec.radio.amateur.antenna
Date: 2009-07-08 19:15:26 UTC
From: Robert Smits <bob@rsmits.ca>
Message-ID: <5b53398d31e37695454f312741851dcd@grapevine.islandnet.com>
Source record: 14310

Hi, folks.

I'm looking for either an E41 or a GENXHA repair kit to replace an element on a cushcraft 10 el 2 meter beam.

Cushcraft won't sell them to me because I live in Canada, and I can't find any Canadian dealer that stocks any, either.

Anyone know of a dealer that a: stocks parts or will order them and b: may ship them to Canada?

Thanks, Bob VE7HS

FWIW, W5GI does say on his web page "Window-type 18 gauge 300 ohm ribbon
works best."

The weather forecasters seem to call anything over 2,500 feet (In the
mountains) so don't blame me. They are still hills and I have hiked
mount Hood so I know what a real mountain is.

If you are willing to vary the length of the series
matching section, a G5RV will indeed cover all HF
bands. The necessary lengths are on a graph at the
bottom of this web page:

http://www.w5dxp.com/G5RV.HTM

Someone was supposed to author a magazine article
about how to perform the length selection using
relays but I never saw it published.

Thank you Cecil ! In other words, your matching unit with the switchable line segments and with the variable capacitor will do the job. Right ?

Yes, it will *theoretically* do the job. But remember
it must be attached to the feedline at a point 12 feet
from the antenna feedpoint. That probably limits the
device to a relay-driven, waterproof box ~30 feet in
the air. It can be done but there may be a better way.

With my notuner dipole, the ladder-line length selector
can be located at the operating position.

With a G5RV, the ladder-line length selector must be
located 12 feet from the antenna feedpoint.

In the antenna context, I think one needs to consider HAAT when making the hill/mountain determination.

I would consider Mt. Wilson (about 5000 ft above Los Angeles) a legitimate mountain.

Is a hump at 13500 above a valley at 13200 a mountain, or a local hill?

813. Tracking down power line noise

Newsgroup: rec.radio.amateur.antenna
Date: 2009-07-09 15:58:38 UTC
From: Rick <ricknj10@hotmail.com>
Message-ID: <Oso5m.222$N5.28@nwrddc01.gnilink.net>
Source record: 14324

I have been wrestling with power line noise here for almost a year.
Power company hasn't been very successful in locating it so I started a
coordinated search
on my own. Thinking if I can tell them for certain which poles have the
problem they can confirm and maybe fix.

The noise is a deafening 20 over 9 on 80 meters which makes DXing on 80 and
160 impossible.
The noise can be heard at my QTH as high as 10 and 6 meters but it isn't
troublesome on those bands because it can only be heard at about an S7 level
when the yagi is pointed at 210 degrees.
I thought maybe my means of analysis might be interesting to discuss and
maybe others would have other suggestions.

There are 7000 volt lines running on a highway past my house. Tracking the
source on 80m seems impossible.
I made a 2 ft square loop antenna, which has some directivity but the noise
level using it seems to not change
much as I travel the highway. On 10 meters, using a 4 ft whip on the car,
the noise is also hard to localize but
seems to increase in the vicinity of 1 mile from home. 6 meters using a
whip is similar. I found that if I'm close
enough that the 6 meter signal is around S7 I can switch to 2 meters and
again peak the noise by driving slowly up and down the road.

So using this technique and driving 2 miles in each direction I have managed
to find 2 spots, one on the highway and one on a cross road, each about 1.2
miles from the QTH. I then built a 432 MHz 8 element quagi beam which
enabled me to pinpoint the offending pole at these two locations. (I have
put a LOT of effort into this project !)

At this time I am waiting (hoping) for a return call from the power company
to verify my dicovery.

So my question for the group - Can either of these locations 1.2 miles
distant cause such horrendous noise levels on 80 meters? Is it possible
that a weaker noise source much closer to me is the culprit or are all of
the power line malfunctions detectable on 440 MHz?

Rick K2XT

Depends who you talk to. I thought California's definition of mountains
was ridiculous when my parents decided to move here. Maybe just the
highest hill in the bunch. Great place to put an antenna though.

It is a mountain. The valley (more probably a saddle at that
elevation for that shallow a depression) is a feature of the same
mountain.

There was an article in QST (or was it CQ?) about building a ultrasonic
"downconverter" to listen for noise sources. Yup, sound.. Many (most?)
Power pole RFI sources are mechanical in nature, and have an ultrasonic
component.

re the Power company. They might be more cooperative if they knew that you could involve the F.C.C. Especially if you decided to "help" them by finding many more sources of noise.

It would seem easier to build a multipole high pass filter (above 200
Hz, say) and feed a many turned loop into it, measure the AC out of
the filter.

Yup. Current (July) issue of QST. A kit that looks very interesting.

If you study the pattern of a small loop antenna, it has a pair of deep nulls. These are the most useful for locating the direction of the source.

The nulls will not be as deep, and not ideally located if the feedline is also part of the antenna, ie if the loop is not well balanced. So much so that common mode current effects may render the antenna fairly useless from a directivity point of view.

You did not mention the measures you took to assure loop balance / insignificant common mode current.

Realise also that you may be trying to locate the cause of the emission, but the loop (properly constructed and used) leads you to the radiation source, and the power lines are very large and very effective antennas. Nevertheless, it should be relatively easy to locate the cause of the emission.

From a practical point of view, I have used a small loop and portable receiver for locating and measuring emissions from BPL over HF, and noise due to fautly transformer bushings, cracked insulators etc. Worked a treat for me. One loop is described at http://www.vk1od.net/antenna/SmallUntunedSquareLoop/index.htm .

I just bought a Telonic RHO-TECTOR TRB-50 return loss bridge off eBay.
It's suitable for swept antenna measurements of 0.5Mhz to 1GHz.
Amazingly, it functions. However, I'm curious as to exactly how it
works and what's inside. Duz anyone have a theory of operation,
schematic, or other useful clues?

The best I have so far is:
<http://www.qsl.net/n9zia/rlb/texscan.png>
which may be the schematic, but I can't tell without tearing it apart
(which with my luck, will probably destroy it). Using my
ohms-guesser, it seems correct.

A possible explanation for why the 80 meter noise couldn't be nulled is that
at most I
was 100 yards from the line and the noise was radiating from all along the
line. That's what it
seemed to be. On the broadcast band, the loop was easily able to locate the
direction of
the NYC radio stations from here in central NJ so I think the antenna was
doing it's job..

> You did not mention the measures you took to assure loop balance /
> insignificant common mode current.

My loop was a square made out of ribbon cable. 1 foot on a side, 7 turns.
The ends of the multiturn loop were attached to a broadcast variable cap.
One turn of the same ribbon cable was the coupling loop, which I connected
to a 6 ft length of RG58 with a BNC connector. The cap peaked the signal or
noise up
nicely.

Understand, that's the conclusion I came to and the reason I switched to
10m-70 cm to
home in on it.

The photo on that web site is essentially what I built, except mine was
multiturn, and had no balun.
I was listening at 2 MHz.

What you described is not IMHO a substitute for an effective balun, so you can expect shallower nulls, and a distorted pattern (ie unequal nulls and the nulls not orthogonal to the plane of the loop.

Although the power lines act as a very long antenna, I have had no difficulty locating BPL injection points using the loop nulls. If you stand under the power lines, you won't get a result, you need to move away from them, preferably at least a quarter wave, and not near other conductors (eg metal rainwater plumbing, other overhead metallic services, metal fences, motor vehicles, buildings with sarked walls etc). That is a big ask, but if you do that, and use the nulls, you should readily get a good set (ie reliable, convenrgent) of cross bearings.

Sure you can look for interference at 70cm or at ultrasonic frequencies... but that won't work unless the source is truly wideband. The other thing is that if you make a complaint, demonstrate emissions at 70cm, and they fix them at 70cm, what do you do if they didn't solve your primary problem. I have seen people do that, and the power company at significant expense solved the reported problem, but not he complainants real problem. Further complaints were treated as vexatious... 'quick as we fix one problem, you find another'.

IMHO, better to measure the problem at the primary frequency, report the real problem, not the cause, but the primary impact on yourself. Depending on the jurisdiction, power companies may not be obligated to eliminate the emission, merely to reduce it to comply with some standard, and in that case, absolute measures of field strength may become relevant.

Don't dismiss the loop and receiver, highly likely that if the regulator attend to establish whether there is a case or not, they will *measure* the emission field strength with a calibrated loop and receiver.

A bit more....

Photo of Texscan RCB-3 inside:
<http://www.qsl.net/n9zia/wireless/rtrn_loss-pics.html>

Photo of Telonic TRB-4 (similar to the TRB-50):
<http://www.mjs-electronics.se/images/Diverse/trb4.jpg>

Telonic is still around, but doesn't have any old info online:
<http://www.telonicberkeley.com>

I tried to find a patent that covers the return loss bridge, but
failed. Plenty of VSWR measuring devices, but nothing that looks like
the TRB-50 or the possible schematic at:
<http://www.qsl.net/n9zia/rlb/texscan.png>

Also, lots of similar devices by Wiltron, Aeroflex(IFR), Eagle, etc,
but no schematics found (yet). Eagle used to have some nifty app
notes on using an RLB on their web pile, but it appears to be trashed:
<http://www.eagle-1st.com>

Drivel: Bing produced fewer results, but far less garbage than
Google. The problem was that most of the hits for both Bing and
Google were various surplus dealers selling MW hardware at exhorbitant
prices.

My local utility has one tech who does power line noise investigations and I'm happy that he solved my problem. He identified three "problem poles" and a week later, the noise was gone.

I can't answer your question about how far power line noise will travel but, since you've put so much effort into this already, this next may be worth doing, too.

One of the tech's tools was an audio detector, which he aimed toward the tops of all the poles on my block. It was a 16-inch clear parabolic reflector with a microphone mounted at the focal point and an amplifier feeding headphones and a meter. The tech was listening for the sound of the offending arc. Never mind the RF -- find the faint sizzling noise by ear!!

For a small fortune, these guys will sell you one: http://www.paradish.com/

You could definitely make one. This article http://www.solorb.com/elect/misc/bige/ illustrates the idea (from a Google search of <"big ear" microphone>) and it looks like he used an old wok. (Are woks parabolic.)

So, if you want to impress the power company ...

Sal

Agree with last posting regarding an ultrasonic receiver, that is most likely what the power company was using. Other equipment for locating powerline noise is a VHF AM receiver and foxhunting type yagi, the signal will be much weaker at VHF which should make the source more obvious when found.
A common feature of powerline noise is that it is intermittent and may disappear for days and vary in intensity from one hour or day too the next. Power line noise is often the result of loose hardware and dirty insulators with the noise being generated by small spark gaps between fittings. Therefore a bit of rain the dry gaps become conductive of the leakage current and the noise disappears. I mention this because if the noise is continuous and un-varying it may not be generated by the powerline equipment, but may be generated from another source and simply travelling and radiating from the powerline. R.F. welding for example.
Power companies or the F.C.C. may have an information brochures for TVI complaints which may show examples of various source types as they appear on TV screens, this may assist in identifying the interferance source.
That shows my age, 'brochures' check their website! And this will not work for digital TV.

If the F.C.C. is anything like Australian authorities TVI will carry more weight than ham radio, therefore if you also have an accompanying TVI problem report that for prompt action.

Best of luck

Peter VK6YSF

Owen,
You bring up some very interesting points, precisely what I was asking for in my original post.
Thank you very much for your assistance.
My theory right now is this:

I have found 2 noisy poles using 440 MHz, both 1.2 miles from me. I HOPED that they would solve my 80 meter problem, once repaired.
As I go lower in frequency, down to 10 meters using vertical whips, I confirm that the noise can be heard farther away, as much as about 1/2 mile on 10 meters.
I am assuming that the 2 MHz component of the broadband noise is being conducted on the lines with very little attenuation for the 1.2 miles to my house where it is 20 over 9 on a Beverage parallel to the lines.
Using my loop at 2 MHz I am essentially unable to get any bearing because the source is essentially a couple miles in length. ???????? And I can't get any significant distance away from the power lines. (One place on my property is 200 yards from the lines but the loop can't determine a null. Yet it does fine with locating BCB stations, so I think it should be usable if the noise was a point source).

> Although the power lines act as a very long antenna, I have had no
> difficulty locating BPL injection points using the loop nulls.
What frequency do you look at for BPL? upper HF (10-20 MHz, where it looks more like a point source?)

> If you stand under the power lines, you won't get a result, you need to
> move
> away from them, you should readily get a good set (ie reliable,
> convenrgent) of cross bearings.

I am failing at that so far, see above.

>
> Sure you can look for interference at 70cm or at ultrasonic
> frequencies... but that won't work unless the source is truly wideband.

This statement puzzles me. Can you please explain more? Can it be that the poles which clearly
show lots of noise at 440 are NOT the ones causing my problem at 80 meters? i.e. can there be defects which generate noise peaking at LF and not detectable on 440?

> The other thing is that if you make a complaint, demonstrate emissions at
> 70cm, and they fix them at 70cm, what do you do if they didn't solve your
> primary problem.

That would be my worst nightmare. That's why I am looking for a better understanding as I asked above.

>
> IMHO, better to measure the problem at the primary frequency, report the
> real problem, not the cause, but the primary impact on yourself.

I did that, starting 11 months ago. I played dumb, just said here's my problem.
The power company guy who has been trying to help me has a wideband spectrum analyzer, and uses a 300 MHz-1GHz LP antenna, hand held. For low frequencies just a pull-out whip. He prefers to use his hand held ultrasonic device with headphones, probably because he has had good success with it. He let me experience it once and it definitely can hear a problem on a pole. So I'd say right now he has the best capabilities at ultrasonic, and I do at UHF (with my 8 element Quagi and sensitive receiver), and neither of us does at low HF.

Rick

>
> You could definitely make one. This article
> http://www.solorb.com/elect/misc/bige/ illustrates the idea (from a Google
> search of <"big ear" microphone>) and it looks like he used an old wok.
> (Are woks parabolic.)

The old style cheap woks are parabolic. The newer ones which have a flat
bottom are not. I have a 24 inch Al parabolic dish. It isn't very
stealthy, but it's lighter and bigger than the woks.

There are some nice features about hunting down RFI problems with sound.
That parabolic reflector can be aimed right at the pole, and in
combination with the short wavelength esp at ultrasonic frequencies will
let you zoom in on the problem pretty quickly. Trying to close up DF
with HF is like trying to change directions on a cruise ship.

> So, if you want to impress the power company ...

If you are doing it near your own house, DO check in with the neighbors
telling them that you are locating the source of noise, and it might
eliminate any interference they might be getting now.

Absolutely. The closest analogy I can think of is RFI in a vehicle. I had rfi sources in my vehicle that were bad on 80, and not heard on other bands, and vice versa. Some sources are broadband, some are not.

>> The other thing is that if you make a complaint, demonstrate emissions at

>> primary problem.
>
> That would be my worst nightmare. That's why I am looking for a better
> understanding as I asked above.

1. Locate what you think is the problem via the method of your choice (though I would suggest multiple verifications. I thiink that is the key to isolation of your noise source.

2. Determine that the problem is also on 80 meters. You might use a radio with a poor antenna. Work your wy towards and away from the suspected source.

3. Realize that if you go looking for RFI sources, you will find more than one. Likely you'll find many.

If you have 30 over 9 RFI on 80 meters, I would not suspect the source to be very far away. I'd expect it to be much closer. It might even be a non-power line source, if you can't locate it on the lines.

> with it.

I don't doubt it, If I fire up my Spectrum analyzer at home, there's a cacophony of signals to look at. The best way to find RFI is if there are harmonics of the signal.

He let me experience it once and it definitely can hear a problem
> on a pole. So I'd say right now he has the best capabilities at ultrasonic,
> and I do at UHF (with my 8 element Quagi and sensitive receiver), and
> neither of us does at low HF.

And there is a clue in that, Rick - I think. There is a possibility that the noise is local. Does anyone have a fence charger, golf cart battery charger, treadmill, CO2 detector, even possibly a wall wart that might be making strong local noises? Can you run your rig on 12 volts and turn off the power at the breaker box? Can you get the neighbors to do the same?

note: saying that you heard the electrical noise, and a little chat about how if there is electrical noise coming from their house, and it

might just pose fire danger might just convince them to help.

If the power goes off, and so does the noise, you've traced it down to a lot smaller area.

You may have tried this already, but those levels are just so high that I have to wonder.

>Some sources are broadband, some are not.

It is quite often related to the pulse width and the pulse shape
coming from the source. Some shapes offer odd harmonics 3-5-7-9, some
even 2-4-6-8 (primary products, that is, as they all offer a full
complement of odd and even).

I am not surprised. The directivity of the 'antenna' varies with
frequency, as may be the power radiated.

Trial BPL emissions that I measured could be heard above the noise on 40m
in a mobile station more than 1km from the trial area. Remember that this
was an emission that its promoters (including the FCC) asserted would not
cause interference.

> I am assuming that the 2 MHz component of the broadband noise is being

That antenna configuration maximises coupling to the currents flowing on
the power lines.

But you are not limited to taking bearings from on your own property.

I will say again, if you are close to the power lines, eg within say, a
quarter wave, the loop mutual coupling with the power lines will reduce
its effectiveness for obtaining a valid bearing.

It is not just a matter of whether a fault (eg a leaking bushing) creates
emission of constant power density from DC to daylight, the lines,
earthing system etc all introduce frequency effects on amplitude. You
could easily discover a relatively noise fault on 440 that is not the
root cause of high 1.8MHz emissions at your location.

My advice is that if you sense emissions at some secondary frequency,
always relate it back to the primary problem. It is OK if the power
company wants to locate faulty insulators with an ultasonic detector, or
a UHF detector, but when they have 'repaired' the fault, the valid test
of whether *your* problem is fixed is measurement or observation at the
frequency at which you suffered interference.

It is just a matter of logic.

For example, if you report a problem on 1.8MHz, and the power company
attends. They report that they found 3 faulty insulators and 1 case of
loose hardware using their ultrasonic detector and sledge hammer and
fixed them. Your problem must now be solved.

No, your problem is only solved when the interference at 1.8MHz has gone
away, it doesn't matter how many other faults they found and fixed while
investigating, until they fix the one(s) that cause your problem, the
problem is resolved.

Ok, they are all techniques for finding faulty equipment... but if they don't measure the emissions at your place before and after, they have not proven that the faults found contributed to the interference problem.

Is that hard to grasp?

> hear a problem on a pole. So I'd say right now he has the best
> capabilities at ultrasonic, and I do at UHF (with my 8 element Quagi
> and sensitive receiver), and neither of us does at low HF.

Again, I earlier made the point that detectable noise is not necessarily actionable. It would be unreasonable to require power line emissions to be undetectable. In that environment, measurement of the emission level either in absolute terms or relative to ambient noise (the degradation caused, if you like) may be relevant to whether the case is actionable.

My experience with BPL particularly, and also with weak signal working is that hams, by and large, don't have much interest in noise, and therefore much knowledge of noise as it limits the communications channel.

An anecdote: A notable VHF weak signal operator reported "I am suffering interference at S9 to 40 over S9 on 2m" led to my question given that he has a high gain array with masthead preamp etc "what does S9 mean?". I was told that his system was 'calibrated', he adjusts the transceiver input attenuator so that the S meter reads zero on band noise.

In the jurisdiction, there is a standard that limits power line emission field strength (specified in uV/m) from power lines, and if it could be demonstrated that the emission exceeded that, there was no question, it needed to be reduced, not eliminated, but reduced to comply with the standard.

But, S9 mean't nothing in terms of the standard, it did not providing a compelling case of non-compliance.

BTW, in this jurisdiction, if a leaky insulator also affects local broadcast reception, a report along those lines is more likely to get

action.

I use a slightly different approach. I have a battery powered marine RDF and all I have to do is align it and follow it to the offending pole, or house. Poles I can usually get fixed if I convince them it is a fire hazard. Houses tend to have people who could care less about your hobby unless you use the fire hazard thing again.

Funny ... how our minds work -- or don't work. I wrestled with the idea of ultrasonic, trying to make sense of snooping for weak, high-order harmonics, vice audible sounds. Despite a quarter century of regular exposure to satellite dishes, personal and professional, I overlooked the fact that dishes are more directive at shorter wavelengths.

Doh!

This is a long thread and I hope I read enough and am not repeating.

I've been involved in a power line noise problems here in McHenry Illinois for the last year and can make a few comments.

There are some very good references on the ARRL Web site. I've read them, one of the books and consulted with Gene Preston, K5GP a pro and one of the paper's authors. They should be top on your list of things to read.

Main page:
http://www.arrl.org/tis/info/rfi-elec.html

This is good, but long:
http://www.arrl.org/tis/info/rfi-elec.html

A good summary:
http://www.ctdxcc.org/powerlines/

Some others:
http://www.arrl.org/tis/info/pdf/0112068.pdf
http://www.egpreston.com/RFItalk.ppt

There's lots more on-line, but these will make you an expert quickly. (:-)...

Power line noise is almost always quite broadband. It won't just be on one band. Therefore, it is best to hunt on the highest frequency available that hears the noise. The noise travels further at lower frequencies and pinpointing a source is more difficult. Three pros I have talked to say this. The author of one of the books uses a modified TV antenna to get up to 900 MHz and above. An Engineer at the equipment manufacturer, Radar Engineers, says the same thing : hhtp//:www.radarengineers.com

They make an ultrasonic ear, a 330 MHz beam/Rx, and a wide range receiver/spec analyzer for power line noise hunting. The local power co here (ComEd) uses all these.

In addition, at higher frequencies you can get more gain in a relatively small size and a resulting narrower beamwidth to better ID the pole. I happen to have the same Cushcraft beam Gene Preston uses (shown in his paper below) and it works nicely to pinpoint a pole or when further away, a region of radiation.

My measurements show the same thing. The noise is at a lower level at higher frequencies, so some gain may be in order. I also use preamps at times.

I have access to the very same ultrasonic and 330 MHz.equipment. I also have a 2M beam, 450 beam, 700 beam and 1296 beam, spec analyzer, yadda, yadda....

We're pretty heavy into this and getting impatient with ComEd.

The ultrasonic will ONLY hear arcing that is in the air OUTSIDE things. Our arrester problem has NO ultrasonic signature (our problem appears to be up to 100 arresters causing noise 15dB above the level when the line is de-energized).
The ultrasonic dish can identify an individual insulator or arcing component.
Hot clamps and ground wires, yes ground wires, can be a significant source. Including the large staples that hold the ground wire to the wooden pole !!

The comments about making sure *your* noise is fixed is right on as well. Identifying the particular signature of the noise should also be done. This is with an O-scope so you can see the time signature (the wave shape) This can also help identify multiple sources.

We currently are waiting for the manufacturer to test 30 arresters that were swapped out. These arresters are 100% tested for RF noise and I'm worried that the test is bad.

FYI:
They also have a 22 blank cartridge in them. If the arrester fails such that is conducts and heats up, the cartridge fires and blows the snot out of the ground connection to free up the line.

Good luck

What you describe is a common Folded Dipole. Whether or not it is
the B&W model can't be determined without a photo. However, in the
form you describe with the "top" wire going straight across with
nothing breaking it, makes it a simple folded dipole. It is cut for a
single band (it is a 1/2 wave long, end-to-end) and is a little wider
in bandwidth that the single wire equivalent that you are probably
familiar with. With a tuner, it can work effectively on several
bands, similar to the ordinary dipole.
It'll actually work at ODD harmonics fairly well without a tuner. As
a 40 meter dipole on 15 meters.

These two wires are in parallel as far as the antenna is concerned,
but the feed point (coax and balun) only sees HALF of the current.
With half the current, but the same power, means the feed voltage is
twice. This makes the impedance four times the ordinary dipole. 2V /
0.5I = 4Z Playing either with the diameters of the conductors (make
the top thicker), or adding more "straight through" wires (on "top")
raises the impedance more since less and less of the total antenna
current flows at the feed point.

Help?

McHenry? I lived there from 1948 to 1955 in the McCollum lake area.
Corn fields everywhere. When I went back in 1993 the old neighborhood was
still there but the cornfields had turned into condo-fields.
I would have hoped the new construction would have put the new wiring
underground so you would not have a problem.
Are things still on poles?

Sounds about like a problem I had. I used an AM 60s vintange shirt
pocket AM receiver to find the offending transformer. When I called up

the power company I gave them the pole number and street address and didnt tell them I was a ham radio operator. Instead I told them it was interfering with me listening to my favorite talk show. They came out the next day.

Thansformers themselves VERY, VERY, VERY rarely make noise.
Insulators, connections and other connecting hardware are the cause.

RE: Mchenry / McCollum Lake

Poles.

I'm actually in Wonder Lake. It's a Wonder it's still a Lake because
no one wants to have it dredged (but they surely want the "lake").

Sad to hear that. I used to swim in it and in 1954 I could watch the
steam engines hauling the daytime commuters to Chicago on the far side
of the lake.
Times change.

Crossposted to rec.radio.amateur.homebrew, rec.radio.amateur.antenna, and rec.radio.amateur.boatanchors

I wanted a dual-meter voltmeter to mount atop an LDG battery booster to continuously indicate input and output voltages, so I rebuilt an old SWAN Electronics SWR-1A meter and now have the faceplate and the internal SWR sensor unit left over.

I'll mail (without charge in the USA) the faceplate to the first person who wants to restore hizer scratched-up SWR-1A faceplate.

Although it weighs less than five ounces, the sensor unit is obviously a bit bulkier (about 5" x 2" x 1.5") than the flat faceplate!-) It includes two integrally-mounted SO-239 connectors, two diodes, two resistors, two capacitors, the dual pot and its knob, and the really-sturdy sensor (but NOT the two 100 microamp meters which I used in my project!-), all connected as they were in the original unit. If someone wants it, it should mail well and shouldn't take too much postage.

849. How Can you Make a VHF TV Antenna for an Attic

Newsgroup: rec.radio.amateur.antenna
Date: 2009-07-15 04:55:11 UTC
From: wdoe999@yahoo.com
Message-ID: <fd0a86cc-2039-485c-b8a5-243f7b7bff03@m11g2000yqh.googlegroups.com>
Source record: 14261
Cross-posted to: rec.video.cable-tv,sci.electronics.repair,rec.radio.amateur.antenna

Hi - I need to receive VHF TV (channels 6,7,9,13) and would like to make a super-duper antenna for inside my attic. I would have thought that I could easily find (simple) instructions on the internet but can't. Does anybody have a simple idea that just uses wire (wire should be easy to attach in an attic).

I've seen some instructions (mostly UHF or DTV) and some of them do calculations for wavelength (let's say 5 feet). And then, with no explanation, the guy just says "I made it 10 feet for better reception". So I ask, can I not then just use the entire length of my attic for super-duper reception? Wire is cheap after all, and I only want to crawl up there once.

I don;t have a PhD in antenna making, so a lot of the instructions/ terms don't mean much to me (dipole, balun, etc). I'm hoping for instructions such as:
1. Cut a piece of 18gauge coppr wire 5 feet long
2. attach one end to a rafter.
3. solder the other end to the centre wire of the coax
4 insert tab A into slot B
etc
etc.

Also, I see instructions that say you should aim the antenna without defining "aim". Do you allign the wire in the direction of the transmission antenna, or should the wire by perpendicular?

Thanks

I'd like the answer to be YES, but it's NO.. If you wanted to make an antenna for just one channel, I'd say yes. I already did it for some guy who wanted a channel 2 antenna over a year ago.
>
> I've seen some instructions (mostly UHF or DTV) and some of them do
> calculations for wavelength (let's say 5 feet).

It's a multi-step process. You have to look up the channel frequency for a TV channel. Then, you take the number 300 and divide it by the frequency. The result is the wavelength. The elements are then cut for approximately a half-wavelength. More details below, if you want 'em.

Multi-channel antennas have multiple elements, all differing lengths. If you have one element, you can expect to receive one channel well and other channels maybe but not as well. A single channel antenna can be made of TV twinlead and attached to a piece of wood. It's called a "folded dipole." More below.

> And then, with no
> explanation, the guy just says "I made it 10 feet for better
> reception". So I ask, can I not then just use the entire length of my
> attic for super-duper reception?

Nope. He's full of it to say that. The only thing that gets longer to make a better antenna is the boom, the center long rod of a long antenna, and it gets longer because additional elements are added to it to improve the performance. However, you have to know how many, how long and where to put them. That's why we study this stuff.

> Wire is cheap after all, and I only > want to crawl up there once.

Crawl up there once and bring a TV antenna with you ... a STORE-BOUGHT TV antenna. Hang it flat from the rafters. A balun is a little matching transformer with side-by-side wire connections on one side and a round coaxial cable connection on the other side. Picture here:

www.summitsource.com/images/products/COTRAN.jpg

Most antennas have two screws for attaching one side of a balun. Connect your coaxial cable to the other side.

> Also, I see instructions that say you should aim the antenna without
> defining "aim". Do you align the wire in the direction of the
> transmission antenna, or should the wire by perpendicular?

The outline of many TV antennas, viewed from above or below, resembles the outline of an arrowhead. That's it. The smaller elements are on the end that's nearer to the TV station. The signal arrives perpendicular to the alignment of the elements.
http://www.radioshack.com/pwr/content/05/72/2112695_31954_thumbnail.jpg is an antenna which illustrates the arrowhead concept. The stations are off to the right side in this picture. I have no idea whether the antenna in the picture is any good.

If you make a single element antenna, you align it perpendicular with the arriving signal. These do work pretty well, by the way.
http://www.wfu.edu/~matthews/misc/dipole.html has some step-by-step instructions for making a folded dipole with ordinary tools.

One last thing: It's not beyond the realm of possibility to make one folded dipole attic antenna for Channel 6 and a second folded dipole attic antenna for Channel 9. The Channel 9 antenna just MIGHT also handle 7 and 13 if you're in a good reception area. You can cable both of them to the TV and switch between them.

Also, to the OP, if you're interested in playing with this some, even
just to the point of seeing what some of the radiation/reception
patterns look like (goes-out signal strength is the same pattern as the
goes-in sensitivity, btw) hop over to http://home.ict.nl/~arivoors/ and
d/l a copy of Arie's version of the 4nec2 antenna modeling software.

There are example files that are similar to typical TV antennas, among
others. You can get a list of channel assignments versus frequency on
Wikipedia.

Hmmm. Wonder where that rail line could have been. None near Wonder
lake now.
Perhaps it was McCullom Lake you mentioned - there *is* a rail line
near it.

It was McCullom lake, about 8 houses to the right of mine down the road.
My grandparents lived about 6 houses to the left, so it was ideal for
me as a young child. I once hiked through the corn fields (now condo
fields) to downtown McHenry and was about 100 feet from a steamer
spinning those huge wheels on startup. That was something I will never
forget, just the raw power and mechanical stuff up close.
That, to me, was American life. I also got into early morning television
DX'ing at about 5:00 A.M. turning the rabbit ears and seeing what I
could get. I got Grand Rapids, Mich once and Racine's test pattern once
and a few more buried in the snow. At any rate I was hooked on radio and
television stuff.

Just saw this thread and some very good suggestions.

One thought. Unless your close to the TV Transmitters, stay away from using wire as the antenna. There is a good reason antennas are made of tubes, not wire. At high frequency, like television transmission frequencies, the current creates a repulsion field that pushes the current away from the center of the conductor. In other words, all the current travels on the outside surface of the wire. Look up the term, "skin depth". At frequencies as low as 20MHz, more than 99% of the current will be within 3 mils of the surface. The only easy way to lower the losses in the antenna is to use large diameter conductors, but since the inside of the conductor carries no current, you don't need metal there, so it is ok to use hollow tubes.

Antenna manufacturers save themselves money by lowering material costs and shipping weight. They use hollow tubes. If you don't care about weight or material cost, go ahead and use solid rods, 1/4 inch, or even 3/8, but stay away from 18 Awg, way too small.

One other thing, nature abhors sharp edges, that's why bubbles are round, so don't use square tubes or sharp bar stock either. Use rounded tubes or rods. Even smoothing and polishing the surface lowers the resistance. When you're done, passivate the surface of the conductors to prevent corrosion over time. [meaning: paint the antenna] Over time, corrosion will deteriorate your antenna's performance. Rounded surfaces also means make your connections smooth with nice transitions. As in, "if it looks good, it works good." You can use aluminum if the lengths are continuous and/or you make connections using constant mechanical pressure, like a "lots of teeth" star washer that has bitten down through the insulating oxide layer held with a bolt.

All in all, it seems a lot easier to buy a fringe field antenna and put that in your attic. But if you do it yourself, hope you're successful, document what you built, and share it here.

The reason usually is physical strength and rigidity. The larger diameter also increases bandwidth, but often this isn't necessary to proper operation.

This is true. However, in almost all cases the loss caused by using wire, even very small wire is still negligible. Exceptions are antennas which are very short in terms of wavelength, particularly at low frequencies. As frequency increases, the length of an antenna of equal performance decreases in direct proportion. However, the loss decreases only as the square root of frequency. So antennas of the same wavelength size become proportionally less lossy at higher frequencies.

> Antenna manufacturers save themselves money by lowering material costs
> and shipping weight. They use hollow tubes.

Another important reason for using hollow tubes is structural weight.

> If you don't care about
> weight or material cost, go ahead and use solid rods, 1/4 inch, or
> even 3/8, but stay away from 18 Awg, way too small.

18 AWG wire won't result in appreciable loss for nearly any antenna.

> One other thing, nature abhors sharp edges, that's why bubbles are
> round, so don't use square tubes or sharp bar stock either.

Square stock is slightly lossier than round, but the loss will be
negligible when unsing any practical size.

> Use
> rounded tubes or rods. Even smoothing and polishing the surface
> lowers the resistance.

Polishing won't make any detectable difference.

> When you're done, passivate the surface of the
> conductors to prevent corrosion over time. [meaning: paint the
> antenna] Over time, corrosion will deteriorate your antenna's
> performance.

It depends on the type of corrosion. But it would have to be severe
before becoming so bad as to cause an appreciable reduction in
performance. Aluminum, tin, and some other metals passivate themselves
by forming a hard insulating oxide layer on the outside. Unless you're
in a maritime climate, copper won't deteriorate in a way that matters,
either. Insulated wire is an easy way to prevent corrosion in an
unfavorable climate.

> Rounded surfaces also means make your connections smooth
> with nice transitions. As in, "if it looks good, it works good."

If only that were true! But unfortunately it isn't.

> You
> can use aluminum if the lengths are continuous and/or you make

This can cause more problems than it solves, if the bolt and washer are
the wrong metal such as steel. A good book on Yagi antenna construction
will tell you about techniques for working with aluminum.

> All in all, it seems a lot easier to buy a fringe field antenna and

> . . .

Loss increases, not decreases, with frequency, in proportion to the square root of frequency. But the conclusion stated in the last sentence is correct. If you quadruple the frequency, wires become four times shorter for the same type of antenna. Assuming you keep the same wire size, this length change results in one quarter the loss resistance. The decrease in skin depth due to quadrupling frequency causes an increase of loss only by a factor of sqrt(4) = 2. The net result is that quadrupling the frequency cuts the total loss in half.

Good grief. Just buy an antenna and open it up in the attic. I've done
it several times and it will cost a lot less in time and aggravation.
Or is your time not worth anything?

Oh, what a shame! Is there no joy in experimenting any more? I have always felt the essence of our hobby has been somebody saying, "Let's try this and see what happens." Sometimes it's an enjoyable QSO and sometimes it's a cloud of acrid smoke. I've had both.

I, too, suggested a store-bought antenna but I went on to suggest other things to try. The OP seems to have an adventurous spark. I vote for ENCOURAGE.

What is the correct angle of the ground legs down of the horizontal
plane in order to get 50 ohm at the feed point ?

Thanks a lot !

About 45 degrees.

Roy Lewallen, W7EL

the answer is: 'it depends'. on the number of radials, their diameter, the vertical radiator diameter, height above ground, etc, etc, etc... my recommendation is to build it and bend until you are happy.

My advice was NOT misleading. Yours was a very poor choice of word. Misleading means the suggested effort would result in moving away from an optimum solution. ALL of my advice leads to better solutions and is therefore "not misleading" and I stand behind my suggestions.

You are very correct on catching the lack of thoroughness addressing 'mixed metal' contacts. Yes, a lot of electrolytic action happens at the junction of dissimilar materials. One must be extremely careful when making such contacts.

Had you criticized my comments by suggesting that many of the efforts involved will not yield noticeable improvement [especially to a novice], I would have accepted that. After working for years in low noise, high performance systems these techniques have become de rigueur for initial construction. The OP probably would not notice improvements except in the most fringe of conditions.

Yes, the diameter of the rod will broaden bandwidth, but elements having ratios on the order of 80:1, the effect on bandwidth won't be very noticeable. Length variations and spacing will have more impact.

Regarding skin depth of a conductor: Always keep in mind that the skin depth equation is based upon the assumption of PLANAR wave. The equation is extremely simple and easily memorized as the square root of 2 divided by three terms:

skin depth(in meters) = sqrt(2/(p*o*w))
where p = magnetic permeability
o = conductivity
w = frequency in radians

for copper, p = 4 pi 10-7
o = 58 MS/m
w = 2*pi*f, with f in Hz

results are in meters, so I suggest using an Excel spreadsheet formula.

skin depth of copper at 80MHz is 0.3 mils! 99% of the current is in less than 1 mil of the conductor.

Using finite element analyses [femm 4.2] techniques it is easy to calculate the impedance of a conductor as long as the dimensions stay below 1/10 of wavelength. For 80MHz that would be 1.2 feet. At 80MHz, 18 Awg copper wire is approx 220 milliohms per foot and 3/8 inch aluminum tubing is approx 36 milliohms per foot. Neither of these impedances would have much impact to the signal coming from the 377 ohm source impedance of free space.

Normally we would have predicted the decrease in impedance by applying the ratio of the increased perimeter reduced by the less conductive aluminum. The ratio of perimeter is 0.375/.04 or approx 9.4, but aluminum is not as conductive as copper so the conductivity ratio is

25/58 for a total change in resistance by approx 0.375/.04*(25/58) = 4.04 improvement. Finite element analyses calculates the improvement to be more than 50% higher than that. [It's caused by the small radius of the wire.] Plotting the current density down into the conductors shows what happened. The 'effective' skin depth in the 18 Awg wire is about 50% less than in the aluminum, all due to the reduced radius of the outside of the conductor. As I said, nature hates sharp edges.

Again, as the element 'taps' into free space the 377 ohms of free space predicts a difference of less than 0.005 dB on the signal. So there will indeed be an extremely small effect from using 18 Awg wire or 3/8 tubing on the received signal strength.

If the antenna were to be much smaller than wavelengths and capacitance were added to resonate the elements, THEN the impedance dfference would become noticeable and affect how much signal is available to the receiver.

Regarding bar stock? picture the current concentrating at each of the four corner edges, with the current not being uniformly distributed around the perimeter. That would almost be equivalent to having 4 parallel small diameter wires mounted on 3/8 inch centers! Really wasted the metal.

Regarding the importance of smoothness: My outside antenna became badly pitted from atmosphere, even with aluminum developing an oxide layer, it still corroded. The roughness lowered the gain of the antenna enough to notice it on the reception from fringe stations. Years ago [and at higher frequencies] we plated metal in our resonators with silver *and* polished the silver to get the impedance down. We measured huge differences in impedance [measured as improved Q] as we polished the surface down to mirror finishes.

Whoever suggested the ARRL Antenna handbook is right. Great book.

Regards,
Robert

There was an article in Electronics World in December 1967 by Harold Pruett titled "Designs for Log-Periodic FM & TV antennas". He used two lengths of hookup wire, attached to a wooden frame in a zigzag pattern, and gives all the dimensions needed. I built one then and it has worked fine ever since, though now there's nothing to receive in this area so I've switched to a UHF-only antenna in the attic. I can mail you xeroxes of the article. I'm adouglas (at) gis.net.

Agreed, my home made loft mounted 4m groundplane has two radials and
it was simple job to get a perfect match using the MFJ259 and some
gentle bending.

Charlie.

Yeah, but if you start at about 45 degrees, you will likely have a lot
less bending to do, if any at all.

Hi to all,

Hope that my question has some sense...: If we double the power
radiated by an antenna (+3 dB), how does it translate on the S-meter
at a receiver 'far' away.. i.e. is the difference in dB on that meter
has some mathematical relation to the 3 dB change at the transmitter?

One S unit is allegedly 6dB. Doubling the power would therefore be
about 1/2 an S unit.

No, none at all. S-meters almost always just measure the AGC voltage, which is only approximately logarithmic. And manufacturers adjust the sensitivity of the meter to please the customers, who don't like "dead" meters. So the sensitivity of S-meters varies greatly from rig type to type and from one end of the scale to the other. I measured the sensitivity of the S-meter on my Icom 730 on one band. Here's how big an S-unit is on my rig:

S1 - S2 1.4 dB
S2 - S3 1.3 dB
S3 - S4 1.6 dB
S4 - S5 2.3 dB
S5 - S6 1.8 dB
S6 - S7 3.2 dB
S7 - S8 3.1 dB
S8 - S9 4.0 dB
S9 - "S9 + 10 dB" 5.6 dB
"S9 + 10 dB" - "S9 + 20 dB" 7.3 dB
"S9 + 20 dB" - "S9 + 30 dB" 6.6 dB
"S9 + 30 dB" - "S9 + 40 dB" 10.5 dB
"S9 + 40 dB" - "S9 + 50 dB" 11.3 dB
"S9 + 50 dB" - "S9 + 60 dB" 13.5 dB

Now let's suppose that you built a new 5 element Yagi antenna and I honestly reported that your signal went from S2 to S6 when you switched to it from your dipole. The gain is really 7 dB, about par for the beam, but you read the postings on the Web and decide that an S-unit is "defined" as 6 dB, so the gain improvement must be 24 dB. Wow! Your modest beam has the same gain as a beam with a 25 WAVELENGTH boom and more than 50 elements! By making that incorrect assumption about the sensitivity of my S-meter, you've overestimated the gain by a factor of 63.

S-meter sensitivities vary all over the map, so any assumption you make about how many dB in an S-unit is very likely wrong, and often grossly wrong.

I've heard the same thing, but the reality is that the S-meter usually
follows the AGC and the signal for S9 could be different for every design.
But Flex radio and others define S9 as 50 uV.

Long time past, I heard that S9 was a noise free signal. But "noise free"
is undefined. 30 dB SNR? 40 dB SNR?

Imagine that your S-meter is perfectly logarithmic and your SNR is 54 dB at
S9. That's one way to get 6 dB per S-unit.

Adjusting the S-meter to read a specific value for one signal strength is simple, and there's often an adjustment for doing it. I think it's fairly common to find S9 to be around 50 uV -- on one band at least -- although I wouldn't be surprised to see a fair amount of variation from band to band. But that has nothing to do with what the difference is between S7 and S8, S8 and S9, etc.

Which is fine if you don't mind possibly being off by a factor of 50 or more, mistaking the gain of a 3 element beam for the gain of a 150 element one. Or you might only be off by a factor of 10, thinking the 3 element beam only has the gain of a 30 element beam. Shucks, what's a few dB anyway.

Only in theory. It is possible to write an expression
which relates an increase in Tx power to Rx antenna power at
the remote site, but I doubt if it would agree with observed
values in the field.

Nail on the head. A step attenunator in line will be the fastest way to determine the linearity of your scale if you can't afford a calibrated generator. FM rigs are all over the map on this because some radios have better limiting than others, and it might be actual limiter reading or some other derived reading.

All of my radios are at least 15 years old before DSP. I was wondering manufactureres that had gone to DSP were using it to make S meter indications more accurate. I am seeing this type of signal correction being made in some of the equipment that I work on that has gone to DSP.

I don't know what that 'expression' might be, but if an increase of TX
power was not matched by a corresponding equal increase of RX power, I
would immediately suspect that a rift was occurring in the space-time
continuum. Whether that corresponds to the 'correct' S-meter reading is
another matter.

You'll need an adequately-screened signal generator to do this test. If
it isn't, the signals which leak out can bypass the attenuator and enter
a not-too-well-screened receiver. If this happens, the results you get
will be false.

Good point. If the signal is off the air it is less likely to be an issue. You need to seriously work on your setup to get better than 60 db of resolution. I homebrewed the 3, 6, 10, 20 step attenuator from one of the ARRL publications and find it quite useful. Output cable is double shielded.

But, with homebrew attenuators, beware of the RF 'jumping over' the
switches at the higher frequencies. This can limit the maximum
attenuation attainable to something which is a lot less than the
switches indicate. [Well, mine did, anyway!!]

Thanks for the references.

Where does the fiction come from that an "S-unit", presumably the marks on our S-meters, is or for some reason should be, 6 dB -- that this is a "correct" or "ideal" value? To me it's the same as "defining" pi to be 3.2, as the Indiana House of Representatives once did. "Defining" an S-unit to be some value has no effect on our S-meters, any more than the proposed Indiana law changed the ratio of the circumference to diameter of a circle.

there are "Many Schools of thought".... but unless someone rewrites the
Laws of Physics, and increase in Tx Output will show and Increase of Rx
Input, on the same path, period. S-meters are NOT necessarily actually
showing Rx Receive Signal Strength, and they are rarely, either linear,
or even Logrythmnic in presentation of what they do represent. In the
Microwave Field if you measure a path, and also calculate that path,
comparing the two will show that they are very close, if you did it
right....

I'm not sure what statement you are arguing against. Has anyone said
otherwise?

>S-meters are NOT necessarily actually
>showing Rx Receive Signal Strength

So what DO they 'show'? OK, they may not 'show' it very accurately, and
the way they work is usually a very indirect way of 'measuring' the
signal power or voltage at the receiver input, but I'm sure that this is
what the do 'show'.

For convenience, most S-meters use the AGC voltage to provide an
indication of incoming signal level. However, some FM-only CB sets have
no AGC, and have to pick off an input level dependent voltage from
somewhere else in the circuit. These are usually VERY inaccurate. What
alternative methods do you suggest?

>, and they are rarely, either linear

No one is disagreeing. S-meters are renowned liars. Mind you, I have a CB set (which has an AGC line) which is converted to 10m, and this has an S-meter which has remarkably consistent 6dB S-points between S2 and S9 +20dB.
>,

One more (in German):
<http://www.s-meter.de>
This one is rather interesting in that you can use the site to make an
S-meter scale.

Software to convert a perfectly good digital receiver data output,
into marginally useful S-Units:
<http://www.seed-solutions.com/gregordy/Software/SMeterLite.htm>

>Where does the fiction come from that an "S-unit", presumably the marks
>on our S-meters, is or for some reason should be, 6 dB -- that this is a
>"correct" or "ideal" value?

Using S-Units is its own punishment. I couldn't find anything on the
history of the S-Meter that would substantiate my guess that long ago
some major radio company incorporated a signal meter into their
receiver. Soon after, everyone had to have one. Whether they did
anything useful is probably debatable. I guess it's not considered a
proper ham radio unless it has an S-meter. For example, the new
Elecraft K3 now has a software S-Meter for those that just can't live
without one:
<http://www.sight.net/K3Meter/>

My guess(tm) is that the 6dB per S-Unit was probably fairly close for
the early tube type receivers. Below S-9 was probably below the AGC
threshold. Above S-9 was more compressed above the knee in the AGC
curve. AGC thresholds in old tube radios was probably a fairly strong
signal, mostly because the RF/IF chain didn't have much gain. 6dB per
S-Unit was probably fairly close and fairly linear below the AGC
threshold.

Roll forward 90 years and we have sensitive receivers that have an AGC
knee at a few dB above the noise floor, with lots of overload handling
ability to maintain a wide AGC range, and sensitivities much better
than tube radios. If I maintain my assertion that S9 is the AGC knee,
there would be perhaps one or two S-Units below S9, and the rest of
the scale would be highly compressed "dB over S9" units. That would
be a rather strange looking S-Meter, but might also be more useful
than the current dual range meter.

I'll give cellular designers minimal credit for replacing the
inaccurate S-Meter with a less accurate 5 bar graph. Not satisfied

with the bar graph abomination, they also invented that rather
non-linear RSSI indication, and then cut it in half again by using
0-100 instead of 0-255.

I suspect that in the future, when we're all carrying FTL sub-space
communicators, Tricorders, and direct thought transmission radios, the
associated projection or heads up display will probably include an
S-Meter.

>To me it's the same as "defining" pi to be
>3.2, as the Indiana House of Representatives once did. "Defining" an
>S-unit to be some value has no effect on our S-meters, any more than the
>proposed Indiana law changed the ratio of the circumference to diameter
>of a circle.

So it is written, so it must be.

Actually, I didn't think of it much until you mentioned it, but
6dB/S-Unit is rather improbable. The base line noise level for an
antique AM radio is probably about 10uv which I presume is S1. S9 is
loosely defined as 50uv. 6dB per S-unit implies a:
9*6 = 54dB
range, which is considerably larger than the:
20 log (50/10) = 14dB
range.

If the 14dB range from S1 to S9 were considered the basis for
calibration, then:
14dB / 9 S-Units = 1.5dB per S-Unit
nowhere close to 6dB per S-Unit

Or, if 6dB per S-unit, and S9=50uv are considered sacred, then 54dB
below 50uv (-72dBm) =
-72dBm -45dBm = -117dBm = 0.3uv, which is rather improbable.
However, that will work for a modern receiver, with fairly good front
end sensitivity and gain.

The chart is interesting. Where the "S-Meter Standard" numbers come from, in blue on the left? If I were to create such an "S-Meter Standard" chart myself without source or authentication, I might be inclined to set S-9 equal to -73 dBm/50 uV and extend the S-values down from there at the popular rate of 6 dB per S-unit.

Chart values do decrease at 6 dB per S-unit but the chart sets -72 dBm/56.8 uV as S-9, vice 73 dBm, 50 uV. 1 dB isn't much to quibble about, but it does make me inquire about the source of the data.

Can anyone elaborate? TKS

BTW, http://en.wikipedia.org/wiki/S_meter provides a similar chart based around 73 dBm as S-9. It sources IARU Region 1 Technical Recommendation R.1. I looked for it; no luck.

hi

Was going to put up some antennas turned via a rotator.

Normally I guess people use some 'flexible' type coax like a
RG213

Wondering if cost was no object is there some coax that is
better rated to withstand this type of repeated flexing ??

Thanks

Pierre,

There is a convention that S meters are calibrated for S9 at 50μV (CW) at the receiver terminals, and the other S units are spaced out at 6dB/Sunit. (Some of the other conventions mean the same thing, eg 100μV EMF as one manufacturer is want to specify).

So, if S9 is -73dBm, then S0 ought to be -127dBm.

In a typical receiver with a sensitivity of around -135dBm for 10dB S/N, the AGC will be delayed until the signal is about 20dB higher than that, or about -115dBm... so an AGC derived solution cannot indicate less than S2 on that scale. Nevertheless they do.

At the high end, extremely strong signals are a challenge for nice scale shape.

In my experience, modern transceivers that provide the facility for three point calibration of the S meter are reasonalby good between around S6 and S9+20dB... give or take. Reasonably means withing a dB or two per Sunit.

S meter calibration is invariably dependent on a particular setup of preamps and front end attenuators. Some of the outrageous 'measurements' one hears of are done in an 'uncalibrated' state (eg preamp ON when it is meant to be OFF.

The S meter behaves fairly similarly to a quasi peak detector, responding to most of the peaks, but not all, and much higher than average power. So applying the S meter to impulse type signals introduces another issue.

http://vk1od.net/software/fsm/ details another method of making more accurate measurements of signal level and field strength using a comms receiver. The system compared favourably in a field comparison with a commercial EMC receiver and active loop on a BPL measurement exercise.

Might be IARU Region 1 Technical Recommendation R.1. See
http://www.algonet.se/~k-jarl/ssa/IARU/smeter.html

Do we have to adhere to it? No, but if enough equipment makers implemented
it, we might have a tough time ignoring it.

Hi Ml:

There used to be a "type" of RG-8 coax called "superflex" that was much more flexable than standard RG-8 (this was back when RG-8 was still a mil standard)but I've not seen it for some time. But I've used RG-213 for years with no problems just remember to leave a big enough loop so the coax is not stressed to much. The kind of coax with the foil under the braid is NOT good for this loop.

I seem to recall that the KWM-2a was calibrated for 100uv for s9. 1db is
well within the resolution of a lot of lab gear. 50uv would be more
appropriate for a modern radio that should be that much hotter. The RST
system of reporting was supposed to be a relative thing anyway.

http://www.arrl.org/notes/hbk-templates/stepatt.pdf
This is the one I based mine on. Fewer sections. The Slide switches are
superior because of lower inductance and the bulkheads help with isolation.
I found there was another version in the TIS section:
http://www.arrl.org/tis/info/pdf/9506033.pdf

I looked again at mine and it is actually 10, 10 and 20 built on G10 scraps.
The blue foam Color TV tuner cleaner helped with insertion loss performance
(if you can find it anymore). It seems to work well and in testing with
several FM service monitors, seems to be within 1db to UHF. I had built it
with T-hunting in mind. For more attenuation I use fixed BNC attenuators.

As the pictures show, there is screening between the switches (even
though it's a bit skimpy on the second unit). Even in the first, for the
ultimate in isolation, it would be even better if there was an RF gasket
on the inside of the top cover which, when screwed down, makes contact
with the tops of all the screens, and makes each switch compartment
virtually watertight.

If a yagi or quad is not practical (trees, power lines, expense, etc.)
a Sterba curtain is a viable alternative. I use a pair on 6M with
one's pattern being N/S and the other's being E/W. One antenna is
matched with a HB 6M balanced tuner while a commercial HF balanced
tuner does the matching for the other.

Depending upon the available room additional bays can be easily added
to a Sterba curtain. Like any antenna HAAT matters. Even so I have
worked EU with a 5 bay curtain mounted 30 feet up.

>What makes this antenna so good as an all band antenna for 160 to 10 m ?
>
A 10M Sterba curtain is a 'good' all-band HF antenna because it does
work better than no antenna at all. A 10M Sterba curtain will show
some directivity on 12M and possibly 15M and 17M as well. Beyond that
it becomes more of a random wire.

That should read:

In a typical receiver with a sensitivity of around -135dBm for 0dB S/N, the AGC will be delayed until the signal is about 20dB higher than that, or about -115dBm... so an AGC derived solution cannot indicate less than S2 on that scale. Nevertheless they do.

Do you know if you could also have worked EU at the same time if you had,
say a 2 element beam
on a 4 ft boom?
Or even a dipole?

Maybe if you had a converted CB vertical your signal into EU would have been
30 db stronger?

See my point?

Hello,

Roy, with all the respect i owe you, you are barking up the wrong tree.
1 S-point should be 6 dB. Manufacturers choose not to do this for
obvious cost reasons. Yet this is the definition, and they should work
on it, especially so now, with digital techniques.
Remains the definition of S9, supposedly different on HF & VHF. I am not
so sure about this, but strongly support HF S9 = 50 uV.

Thanks for your enlightening comments on this newsgroup.

You figure out these things when you have more time than money or sense. I might not make it to mars before someone with a budget though.

Actually it turns out the second version might have better isolation, because it turns out coupling between the resistors and the switch terminals is more unwanted than between the attenuator sections themselves. But it is wise to remember that probably 20db at each switch is the most to be expected because of the coupling within the switch. It is probably a good thing to compartmentalize also, to realize a maximum combined attenuation with all sections engaged. His worry seemed to be trying to keep 50 ohms between sections when all switches are bypassed, but I doubt that there is 50 ohms through the switches themselves. Of course if any section is engaged, the return loss would make it a moot point.

I guess in the end, the switch itself becomes the limiting factor in the performance of the thing, as with any RF switching project. Hard to find non-inductive resistors too but surface mount chips might be a good answer to that.

What kind of vertical provides 30 dBi?

Gain estimates for Sterba curtains are all over the map, 2 dBi per bay
is a commonly considered figure. A 5 bay curtain's gain is better than
any two element yagi or a single dipole. It may have been possible to
work EU with a either the yagi or a dipole but I have neither.

>See my point?
>
No. There is no place at this QTH where a yagi can be mounted within a
hundred feet of the shack. Even with a HB yagi the required coax,
mast, rotor, rotor cable, guy supplies etc. represent a substantial
expense. Window line, insulators, rope and #14 THHN is a lot less
costly. Of course if someone wanted to gift the funds ... hi,

My seven-bay curtain was built and hung at 50 feet in less than day
with no assistance. I don't believe that can be done from the ground
up with a plumber's delight. Wire antennas don't require antenna
parties to go up or down. This makes both experimentation and
maintenance very easy,

My primary HF antenna is a full-wave loop for 160M. This antenna is
also fed using a balanced tuner and window line. The loop works well
on 6M but lacks the directionality on rx that a curtain provides. With
my curtains another benefit is going from NS to EW only takes the flip
of a switch.

There are situations where a Sterba curtain is a more viable choice
than a yagi. In my case even if trees and power lines didn't preclude
mounting a rooftop yagi, the landlord might not consent to such an
installation.

Many CATV modules use a gasket made from the equivalent of a sheet of
spongy foam rubber/plastic backed with BacoFoil.

I will second the OSJ 146/440. It is a "side by side" dual band
J-pole so it is only the height of a basic 2 meter J-pole, very
sturdy, and does not require a ground plane. Mine is on the roof, but
I have a good friend who has his installed in the attic of a condo. He
hears and transmits very well.

923. Question on Antenna Voltage

Newsgroup: rec.radio.amateur.antenna
Date: 2009-07-21 22:19:27 UTC
From: AndyS <andysharpe@juno.com>
Message-ID: <6393ff9e-5924-4e79-bd65-25d7ff8322f8@k19g2000yqn.googlegroups.com>
Source record: 14185

Andy asks

When one uses the equations for a loop antenna to determine what
voltage will be developed at the antenna terminals due to a passing
signal,
is the calculated voltage with the antenna terminated in an open
circuit,
or a resistance equal to the characteristic impedance of the antenna,
or some other load ?

I haven't seen any of the texts state specifically whether the
voltage
is open circuit or otherwise....

Same question for any antenna ---- if I use Power Density times
Capture Area , it implies that the antenna is terminated in a
resistive
matched load....but I haven't seen it specifically stated. Perhaps
the
issue is too obvious to write down. But I would like to see it.

I would appreciate some small discussion on this. It is a very
simple
thing to clear up if anyone here has first hand knowledge of the
issue.

Thanks, W4OAH

The simplest case is to specify that the antenna is terminated in a resistance equal to its own radiation resistance (e.g. 73 ohms for a thin-wire dipole) then the sums are made straightforward and equal amounts of power are developed in the termination and the antenna. If the antenna is essentially lossless, the power 'dissipated' in the radiation resistance is re-radiated.

Open-circuit voltage wouldn't be a good guide to its coupling factor for a lot of common antennas (which are called on to produce current) but, of course, it works fine for active monopoles.

Chris

What sort of loop are you asking about? If it's a small loop (that is, small in terms of wavelength):

> or some other load ?

Most likely open circuit. If not, it would be terminated in the complex conjugate of its impedance as a source, which (for a small loop) will be a very large impedance consisting of a large amount of inductive reactance in series with a very small resistance.

Here it would be terminated in the complex conjugate of its impedance, and the result of your calculation -- power -- would be the power dissipated in that very small resistance.

The phrase "resistive matched load" you used above is an oxymoron because of the very large reactance required for a matched load.

2m J-pole antenna is my recommendation. It delivers a reasonable match on 70cm, too. One drawback is the elevation pattern at 70cm -- the major lobes are not at the horizon and much of the power is wasted if you're working terrestrial. The antenna is about 57 inches tall and, as an end-fed dipole, requires no ground plane. Google <j-pole ham build> and take your pick from the many articles.

Of course you could make two j-poles, one for 2m and one for 70cm. They can even be "stacked" all in one piece with separate feedlines. Tricky. Saw one article years ago but can't find now.

A single structure dual band antenna is here in the ARRL Members Only Section:
http://www2.arrl.org/members-only/tis/info/pdf/0010050.pdf

I see that they have a 4.8/5 rating on eham.net. I will definitely look into them.

From the picture, it looks like one of the poles has a SO239 connector, but the others don't. Are
the two other poles passive?

What's the radiation pattern?

Another antenna I've been looking at is the Diamond X50A.

Hello, and years ago I needed to do some electrically-small antenna tests at one of our NRL field sites. These tests involved the entire 2-30 MHz band so it was always a challenge to find a quiet spot (We were using rack-mounted R-390 receivers in the testbed). In addition to the usual atmospheric noise and radio station interference there was always what appeared to be some local electrical noise that came and went and was worse on some days than others. A.C power to the site was brought in via utility poles to pad-mounted step-down transformers.

One of my cowarkers suggested a technique for locating interference that he claimed to have success with in the past: A hand-held sledge hammer is used to whack the utility pole while listening for an associated change in noise on a cheap MW band transistor radio tuned off-station. My cowarker claimed that if a cracked insulator(s) was the perpetrator this technique would confirm it.

We tried this technique at the site but with no success. We also drove down the site access road about 1/4 mile with a car AM radio tuned off-station and also got the interference in the vicinity of the utility poles. As a result we never did locate the source. My conclusion was that while the interference was being coupled to the antenna-under-test it may have been generated at a considerable distance from the test site and conducted via the overhead power lines. Sincerely, and 73s from N4GGO,

Most any mobile antenna may be mounted using radials vs. metal plate. Metal
plate need only be 19" radius disk for maximum performance. My favorite is
the Larsen NMO270. Overall height is 35" maximum with better gain than a
J-pole. You can make your own base radial mount or get one of theirs.
Available through AEA or HRO. the NMO is the Motorola mobile mount so
mounting solutions abound by a great many antenna manufacturers.

Even considering an ideal S-meter having a perfect one-S point-per-6 dB
response, the answer to the original question is that only in theory doubling
the transmit power turns into a 3-dB increase in S-meter reading.

In practice what the S-meter "measures" is the sum of the "wanted" signal power,
plus the background noise power (which on e.g. 160 meters could be quite high),
plus possibly the power other signals falling in the receiver bandwidth. If the
wanted signal is not strong enough to overwhelm al other contributions, doubling
the transmit power will not turn into a 3-db S-meter reading increase.

It would have to. Any additional power to the general spectrum is
going to raise the power in the spectrum - even if you cannot
distinguish it. That is, afterall, how the spectrum gets to become so
noisy. If you are tuned to the radiator that has gone through a power
boost, then your S-Meter should indicate it.

Yes, but not quite 3dB when transmit power is doubled. A 3-dB increase would only occur if the "wanted" signal would be alone in the receiver bandwidth (viz no background noise, no interfering signal).

Hello Andy,

In some cases you can check it yourself by calculating the no-load
voltage, compare this with the published data.

As for a single turn coil:

EMF = 2*pi*f*Aloop*B (all rms values), Pdens = E*H,
Zo=377 and B = u*H

EMF = 0.41*A*f*sqrt(Pdens), f in MHz, A in m^2, single turn.

Wire length of loop < 0.25 lambda. Pdens = plane wave Power Flux
Density (W/m^2).

Formula can also be applied on multi-turn loops, as long as the
operating frequency is far below the self-resonant frequency of the

multi-turn loop.

When: (reactance of coil) < Rload, output voltage is almost equal to the unloaded voltage (EMF). For narrow band operation, you can add a capacitor in series to cancel the inductance. You will get the EMF across an about 50 Ohms resistive load (as radiation resistance of small loops is far less then 50 Ohms). I used this approach on a single turn loop made out of strip material (the strip material is to lower the self inductance of the loop).

Of course when using good matching, you can get more output power with a given PFD.

Generally spoken, antennas for EMC measurement purposes (mostly not well- matched for the HF and lower range) are mostly specified with a given load (mostly 50 Ohms).

For antennas specified with capture area:
Pout = (capture area)*Pdens.
Capture area = gain*lamda^2/4pi. Gain NOT in dB.

The actual loaded voltage depends on the input impedance of the antenna. The no load voltage is twice the loaded voltage, only when the antenna is perfectly matched to a resistive load.

When the gain, antenna factor or capture area is specified under non-perfectly matched condition or is specified for a perfectly matched non-resistive load, the EMF is generally NOT twice the loaded output voltage. As an example you can consider a non-tuned loop.

I hope this helps you a bit.

Best regards,

Wim

Google "Copper Cactus" for that one.

I was never able to figure out the design details of the "single
feedline" Copper Cactus - it uses some internal matching stubs which
were not well-described.

The dual-feedline Copper Cactus worked out pretty well for me - I used
it for around 5 years (roof-mounted) until I replaced it with a
commercial tri-band antenna.

>but the others don't. Are
>the two other poles passive?

The Arrow is an "open-sleeve" J-pole design. The other poles aren't actively fed, but make up a critical part of the antenna design.

A standard (traditional) J-pole is an extended zepp. It consists of a half-wave end-fed radiator, connected to a transmission-line matching section (nominally a quarter-wavelength). The matching section is usually made up of an extension to the radiator, and a second element located an inch or two away.

The matching section is usually shorted at the bottom, and fed at a tap point an inch or two above the short... a point at which the high impedance of the end-fed half-wave radiator has been transformed down by the transmission line to something close to 50 ohms.

An "open sleeve" J-pole (which Cebik calls a "nontraditional" J-pole on his web site) is a bit different. It's somewhat shorter (the long arm is less than 3/4 wavelength), the short arm is longer than 1/4 wavelength, and it's fed differently (at the bottom, with one arm being grounded and the other being insulated from ground and fed directly from the feedline). Cebik's website has a very nice discussion of it.

The Arrow OSJ is actually two open-sleeve dipoles, in parallel. The longest arm and the shortest arm are grounded, and the medium-length arm is connected to the hot side of the feedline.

On 2 meters, the long and medium arms form an OSJ and are active... the short arm is simply a grounded stub which carries very little current and doesn't radiate much.

On 70 cm, the medium and short arms form an OSJ and carry most of the current. The long arm probably carries a small amount of current, but since it's a couple of wavelengths long its radiation resistance is high and its current flow and radiation are only a small percentage of the total.

>What's the radiation pattern?

Very similar to any other half-wavelength radiator... 0 dBd, plus or minus a few fidgets.

The Arrow OSJ is not actively decoupled from the feedline (there's no balun) and thus there may be a small amount of RF current flowing on the outside of the feedline, and some amount of disturbance of the pattern. The amount of current on the feedline will depend on the details of the individual installation (e.g. the length of the feedline). I don't think the effect will be significant in most installations; reflections from the ground, building structures, etc. are likely to alter the pattern just as much or even more.

You may, if you choose, mount the Arrow on an insulated mast, and include some sort of choke in the feedline (e.g. a small loop of a few turns in the coax, or some ferrites) in order to reduce the effect of feedline radiation.

I think that the Arrow is a good performer and a good value. You can even make 'em yourself if you wish - Arrow sells the parts individually and (last time I looked) had complete construction dimensions and plans somewhere on their web site.

Just in the past few months or more there was a nice article and
product written in either CQ or QST magazine. I have just gone through
the Index for every issue for the past 4 or 5 months of both magazines
and can not find that article.... very frustrating.

The article outlined a product (kit?) for an untrasound receiver and
illustrated how the author configured it in order to find power line
interference from just the sources you are looking for. It is a much
more elegant solution than trying to use radio and usually pinpoints the
problem right down to the proper cross-arm on a pole.

Wish I could provide more info but I've spent the last half hour
looking for this and am apparently over-looking it. ... sigh

good luck

You should put a wanted ad on qrz.com & eham.net since
a lot of hams check the want and sale ads every week.

Hi

Thank you very much for responding. was hoping more might respond
to what I thought was a fair question.

Interesting wonder why you don't recomend the foil type I guess the
extra flexing would damage it??

Perhaps i can just find some double braided shield then...

thanks

What are the pros and cons of an Arrow J-pole versus a Diamond X50A pole?

The Diamond X50A has a somewhat higher gain than the Arrow on 2 meters (about 2 dB higher, if I'm reading the stats correctly) and a significantly higher gain than the Arrow on 70 cm (about 5 dB higher).

The Arrow is about 6" shorter than the Diamond (might fit into an attic space where the Diamond will not), has been tested at power levels of up to a kilowatt (the Diamond is rated for 200 watts), and costs only 40% as much as the Diamond.

The Diamond has decoupling radials, and I infer that it's less likely to have a feedline-RF situation than the Arrow - its actual pattern may be more consistently like its theoretically-calculated pattern.

The Diamond looks more like a traditional antenna... the Arrow is more likely to get "What the >bleep< is that thing?" questions, if mounted outdoors.

The Arrow may be easier to field-repair, since it's mostly just aluminum angle and rod stock.

Yes. Not only does the foil shield break up, but the abrasion between the dissimilar metals causes noise

> Perhaps i can just find some double braided shield then...
>
A good 95% + shield like Belden 8214 or eq. foam type with stranded center conductor is the best. Extra shields will complicate matters. If you have multiple runs, the crosstalk between cables will me much less than the antennas talking to each other anyway unless you have a lot of vertical separation. It is good to use double shielding on duplexers and hardline on fixed antennas. When going around a rotor, you will have maximum life if you provide strain relief and broad loops like the remote broadcast trucks do. The coax will go bad at the loop first. Another answer is to use hardline up the tower and 8214 or RG-214 and N connectors for the rotor jumper, and replace it occasionally. Of course the connectors must be strain relieved, wrapped and well sealed to avoid any mechanical disturbance or water intrusion.

Wow, 5 dB extra gain for an extra quarter wavelength, and 2 dB for an extra 7/100 wavelength of size. That's quite a trick!

Do you maybe mean to say that the Diamond has a somewhat higher *claimed* gain than the Arrow? If we're looking for high claimed gains (and claimed power handling capability for that matter), some of the CB whips should take the prize.

Roy Lewallen, W7EL

You're quite correct. I'm going by "claimed" gain figures, and those
that Diamond cites do sound a trifle high to be believable.

I don't know what the actual gain is, but Diamond has been in business a long time, and I've never
seen any reports of them misreporting gains.

Does the Arrow have any gain? I thought it was close to 0.0. If it does, how do you know it's
correct?

The overall rating for the X50A on eHam.net is 4.7/5. The average rating for the Arrow J-pole is
4.8/5. It sounds like both products are highly regarded.

So the Arrow is rated 0.09 dB higher than the Diamond. That's probably realistic.

Roy Lewallen, W7EL

Rather than punching a hole in the roof to accommodate your attic co-linear,
how about the ELK 2m/440 log periodic or Cushcraft A270-6s. A small Yagi is
not so directional that you can't use it for the local stuff while pointing
it yonder for a few weak ones.

I want to be able to hit a dozen or so repeaters in different directions, so I don't want a directional antenna.

I believe I have enough height in the attic for the X50A. If I measure and come up short, I will
get the X30A instead.

959. Antenna Wire / Downlead Connector

Usually when a wiring diagram is drawn the wires cross each other as
they go to different placeds
To differentiate between wires crossing and a wire connection one
usually places a dot to signify an electrical connection.
Art

Cool, Art; thanks. Therefore, I use an insulated wire for the the Downlead, solder it to the horizontal antenna wire, and slip it into the red SW ANT plug on the side of the radio. A 10 Ga wire, then, connects the black GND plug to the ground. Thanks. That answers my question.

slade

most TV antennae used folded dipole as it gives a wider
bandwidth. Then there is a 300-75 ohm balun. This is a
2:1 stepdown transformer.
What if I want one channel? Would I be better off with
a simple dipole and a 1:1 balun?
This should give me twice the voltage?

err, no. Adding elements reduces the impedance and it becomes something
like 75 ohms.

> This is a 2:1 stepdown transformer.

no it isn't

> What if I want one channel? Would I be better off with a simple dipole

Hello,

When properly matched, there is no difference in performance (output POWER) between folded dipole and HW dipole.

Mechanical advantage of folded dipole is that you do not need to make an insulated support. For narrow band operation (no parasitic elements), you can use an electrically half wave piece of 75 Ohms coaxial cable to do the matching and bal. to unbal. conversion.

When making yagis, the purpose of the folded dipole is to get impedance close to 75 Ohms. Addition of the parasitic radiators reduces the impedance of the driven element. When using a HW center fed dipole in a long yagi, the impedance of the yagi will be far below 75 Ohms.

Best regards,

Wim

While reasoning on antenna systems reciprocity (i.e. same gain / losses for transmit and receive), a case occurred to me which, at first glance, does not look to be reciprocal (whilst it obviously is in reality). I consider that case fairly instructive, and I then propose it to you for your comments.

Let us consider:
- an antenna having a resistance of 150 ohm (no reactance).
- a coaxial cable having 50-ohm characteristic impedance and a nominal attenuation of say 2dB. For calculations simplicity, let us assume that its length is a multiple of half wavelengths.
- a transceiver having 50-ohm impedance (both RX and TX).

During receive the SWR on the cable will be 1:1 (the RX impedance matches the cable impedance), and cable attenuation will then stay at nominal (i.e. 2 dB).

During transmit, the antenna impedance mismatch will cause an SWR that varies along the cable, ranging from 3:1 (at the antenna-end) to about 1.9:1 (at the TX-end), and the TX will so see an impedance of about 95 ohm (or 26.3 ohm if you will). Due to the SWR, the cable will then show an extra attenuation that does not occur during receive. The ARRL Handbook graphs quantify such extra attenuation as about 0.8 dB.

The different cable attenuation between receive and transmit may erroneously lead someone to considering the system to be non reciprocal.

My simple explanation of why the system is instead reciprocal is the following:

- during receive the 150-ohm source (i.e. the antenna) which sees a 50-ohm load will be subjected to a mismatch loss that can be easily calculated to be about 1.25 dB.

- during transmit the 50-ohm source (i.e. the TX) which sees a 95-ohm load will also be subjected to a mismatch loss but of lower value, that can be easily calculated to be about 0.45 dB.

The mismatch loss difference, i.e. (1.25 - 0.45), is perfectly compensated for by the extra cable attenuation of 0.8 dB. This witnesses why the system is reciprocal (even having based calculations on a quite simplified model of reality).

73

Before accepting statements like this, and that of the previous poster, I would encourage those who can to take a look at the terminal impedance of a good-quality (i.e. professional) Yagi such as one of those manufactured by J-Beam - which use a folded dipole as the driven element and use a half-wave balun (insulated wire wound around a metal rod) to interface with the co-axial tail. Those I have looked at have had terminal impedances close to the specified cable impedance at their design frequency ... they have certainly not been much lower than 50 or 75 ohms.

My own understanding is that they use a folded dipole for its advantageous bandwidth, so they can manufacture, and their dealers stock, a smaller number of models to cover a specified wide bandwidth (i.e. the bandwidth of the antenna is determined by pattern and impedance considerations on account of the array more than the driven element). I have also noticed that the

physical length of the folded dipole they use is related to the cable impedance (i.e. between 50 and 75-ohm versions for the same frequency band) whilst a similar type of balun is used.

Some cheap television aerials are sold with co-axial connections directly to a folded-dipole 'driven' element but this is likely a cost-cutting measure, which impairs ruggedness of the installation against household RF noise.

Chris

makes sense to me, but that is not talking about 'antenna' reciprocity, that is the whole system. the antenna ends where it attaches to the feed line.

The questioner asked: "Do you align the wire in the direction of the transamission antenna or should the wire be perpendicular?"

I saw no answer to his question. So reluctantly I respond. Most antennas are broadside to the direction of transmission but not all.

One simple and effective TV receiving antenna has its wires on a diagonal to the direction of the transamitter. The antenna has a diamond shape and is called a thombic. Its long axis is aligned in the direction of the station. Each of the four sides of the rhombic is 2 or more wavelengths. As size increases so does the antenna gain. Bandwisth is very wide covering several TV channels.

Channel 2 was the lowest frequency TV channel widely used so it had the longest wavelength (50 MHz & 6mtrs. or 68 ft.).

Nothing is critical about a rhombic. One was proposed as a "Super TV Antenna" in the March 1967 erition of "Electronics Illustrated" magazine.

It is 64x24 ft. Each of its 4 sides is about 34 feet. An 820 ohm, 2 watt carbon resistor is used to terminate the junction of the 2 sides of the rhombic at the end which is pointed at the station to be received. The rhombic is narrower than long. The opposite end of the rhombic is connected to 300 ohm twinlead which extends to the receiver, but higher impedance line would be marginally better as the rhombic is effectively a wide place in an 820 ohm transmission line.

I`ve built and used many rhombics. They all were satisfactory in spite of somewhat ragged patterns. They are capableof high gain and extreme bandwidth. They require much space and 4 supports but construction is simple for the minimalist model.

Best regards, Richard Harrison, KB5WZI

The multiplier is 3.28 to convert meters to feet, so I should have written 19.68 ft..

I also intended to warn that an attic is usually unfriendly to antennas due to the proximity of metal pipes and wires which interfere.

Best regards, Richard Harrison, KB5WZI

I'm bringing an HF rig to the mountains of Colorado next week. I just finished assembling a travel kit of dipole elements for 10, 15 and 20. I have ropes, pulleys, wire elements, baluns, cable, connectors, a tuner, VSWR meter, etc. There's no electricity except for a very few generators, so typical urban noise should be absent. Joy!

What's the custom for transmitting my I-D? I think it's "KD6VKW, PORTABLE ZERO." It might be "KD6VKW, STROKE ZERO." I've heard both variations and I searched for about 20 minutes and only found that in the US I'm apparently not legally required to transmit anything after my callsign. It's optional.

I know the county and grid square. Since some hams hunt counties and grid squares, should I include either when I call CQ? Opinions, please.

A couple of things.
Don't forget to take a couple of stakes and a fairly large hammer, you might need them. To hold the ends of those antenna lines, or maybe for a piece of gear that is frustrating you?

As for encluding everyting someone might possibly want to know in that 'CQ', it'd probably take 15 minutes to send it. Why not just let'em ask when they answer your CQ?

I don't have access to that book or the illustration so can't say what
that 'dot' represents. One way to figure it though, is that feed line
a singe conductor, or two conductors? If it's a single conductor it
probably just makes a direct connection to the antenna. If it's two
conductors, there's probably an insulator of some kind there, and each
conductor goes to one 'side' of the antenna. Make sense>

You are not required to send anything but your call as you mentioned. If
you want to , you can add almost anything after it. For voice , portable
is/was used. The Stroke was used in CW.
If using voice, you may want to say "portable Colorado" if you are not
getting any response to your CQs.

True, but its not going to help drive a preamp which
is matched to the input Z.

"Portable" is usually interesting enough to get someone's attention.
Inevitably, if anyone happens to be tuning around and finds you and cares to
answer a CQ at all they will call you. If you give out all your exchange in
a CQ, why should they call you if they already have every thing they need

from you?

I have no problem with a continuous beacon as long as you are QSK but there are a lot of people out there that have their own ideas of how things should be done and want to police others, so good luck. I have better luck giving another station a call. This at least occupies the frequency with chatter that people can find, then QSY 10 kc and give a call. If you weren't too boring, you will have a pile up. If you don't hear anyone on the band at all, maybe the band is dead.

Reciprocity means the pattern will be the same transmitting or recieving.
There are other things that may not be reciprocal though. The ionosphere
may change the polarization of the signal. Transmitter and reciever may
have different loading capabilities and the system may change due to heating
from resistive losses under power.

This may be true but there are other advantages/benefits.
Given that parasitic elements lower the resonant feedpoint
impedance and the target feedpoint is 50 or 75 ohms:

Which driven element makes more sense? One that starts
out with a feedpoint impedance of 75 ohms or one that
starts out with a feedpoint impedance of 300 ohms?

Hello

I have bought an antenna in secondhand an antenna MFJ-1782. I have some problems to obtain good results for the SWR .My antenna is in vertical polarization. I use this antenna with a battery..

I have only a good SWR in the ten meter band (1.1) but when the frequency degreases , the SWR increases very rapidly . On the 20 meter band , the SWR is near 3-3.5 - The coax is H100.

I tried with differents lenghs of coax . (5 , 10, 15 meters) and the result is the same.

I don't know what I must do.

I write you (in bad English and excuse me) to say if you have a solution to my problem.. I thank you in advance

Start with:

http://www.mfjenterprises.com/support.php?productid=MFJ-1782

You can download an English version of the manual. Hopefully that will help.
If you have trouble understanding the manual, you could ask here in your
native language and someone may be able to translate the parts you need, or
explain it in simple English that works for you.

If that does not help. MFJ has a technical support form you can fill in and
they will answer you by email. I had a question about a qrp rig I bought in
1995 and they are still selling a version of. I filled in the form and got
an email back the next day from the engineer who designed it.

You can also call them at 1-662-323-0549. Many people have Internet phones and
the call would be a few pennies a minute or free. If you don't a neighbor or
friend might.

Even if you don't feel comfortable speaking in English on the telephone,
they may be able to help you anyway, or find someone who speaks your
language. It's worth a try.

Geoff.

I think you've misunderstood what I wrote. A J-beam Yagi such as http://www.amphenol-jaybeam.com/datasheet_files/7043xxx.pdf has a folded-dipole driven element _and_ a half-wave line balun interfacing it to coaxial cable. This type of balun, as I expect you know, transforms the dipole's impedance down by a factor of four so a nominal 300 ohms is matched to 75 ohm cable. When 50 ohm cable is specified, the same type of balun is used but the length of the dipole appears to be slightly reduced ... but now I'm repeating myself. In such a case the parasitic elements can't be reducing the feed-point impedance of the dipole very much.

Incidentally, the cable 'tail' is conventional 50 or 75 ohm cable (i.e. it doesn't act as a transformer).

As I understand it, feed-point impedance is one of the several variables involved in Yagi design, along with aspects of the radiation pattern such as main-beam width, first and other sidelobe levels, and front-to-back ratio, the resulting directivity gain, and the frequency response of all these factors. Professional antennas may not be designed for maximum gain.

Chris

Loosen up, Sal! :-)
And, mix it up!!
You're not going to call CQ one time, and one time only!

Sometimes "CQ FROM KD6VKW PORTABLE ZERO"
Sometimes "CQ FROM KD6VKW PORTABLE COLORADO"
Sometimes "CQ FROM KD6VKW DELTA MIKE SIXTY EIGHT"
Sometimes "CQ FROM KD6VKW"
Sometimes "CQ FROM KD6VKW HIGH ATOP FAIRVIEW PEAK"

Let'em know on the other end that you're not just an "electronic voice "keyer".

(Although I have *no* idea what this has to do with antennas...)

Enjoy Colorado!

988. Re: Obtaining electromagnetic radiation from accelerating electrons

Newsgroup: rec.radio.amateur.antenna
Date: 2009-07-27 21:43:10 UTC
From: "Peter O. Brackett" <none@no-such-domain.nul>
Message-ID: <q4-dnRlj8OrpgvPXnZ2dnUVZ_vGdnZ2d@earthlink.com>
Source record: 14250

Richard:

Actually [cfr: Feynman's Lectures on Physics] it is not the acceleration of charge that produces photons (radiation), rather it is the rate of change of the acceleration of charge that results in radiation.

As we all know, 'velocity' v is the rate of change of distance or space s, expressed in terms of the differential calculus this would be written in scaler form as (v = ds/dt) while 'acceleration' a is the rate of change of velocity v, (e.g. a = dv/dt = d(ds/dt)/dt). In Engineering and Physics, the next level of differential change or rate of change of acceleration is usually termed 'jerk'. Jerk j then is j = da/dt. Jerk is not often mentioned in elementary presentations of mechanics, but as far as I know even with more in depth presentations there are apparently no 'standard' terms for higher derivates of distance change than jerk. [distance, velocity, acceleration, jerk, and then...]

Since, like their relative, the exponential functions, the sinusoidal functions, sine, cosine, etc... "sort of" replicate each other every time they are differentiated the higher order differentials of each such function 'look' simply like a scaled version of the other derivatives. Thus, for sinusoidal waveforms, which are the usual functional form assumed for most Engineering work, it is relatively easy for one to come up with a mathematical expression which provides exact values for radiation levels in terms of charge acceleration instead of charge jerk. Since of course if the charge velocity is sinusoidal, so is the acceleration and so is the jerk.

Notwithstanding that there are well known formulas that relate radiation levels to charge acceleration for sinusoidal waveforms, it is not charge acceleration per se that causes radiation. Charge jerk causes radiation.

If one desires an exact formulation for radiation caused by charge motion then perforce to be exact for general non-sinusoidal waveshapes such formulae must be related to charge jerk not acceleration.

If you do not have access to Feynman' Lectures on Physics (I believe he discusses this in Vol. 3) there was a recent more accessible discussion of this topic by the editor of QEX in an article published in QEX several years ago.

I have plenty of experience with a dead band. Don't we all?

I have generally had good luck throwing out a CQ. I offer
as many CQs as I answer, just to maintain a balance.

San Diego isn't much of a foundation for a pileup but Gunnison County,
Colorado might be.

Your English is fine.

You did not say if pressing the tuning buttons on the Loop Controller is making any change. The SWR should change and the UP or DOWN LEDs should turn on. Could the polarity of the battery connection be incorrect? Could the battery be too small or too weak to provide the needed current to move the tuning motor?

http://www.mfjenterprises.com/man/pdf/MFJ-1782.pdf in English. I could not find it in French.

I searched at google.com for

mfj 1782 francais

I found this:

You're fine. Sometimes it's just quiet.

Art is in an institution or fresh back with good meds. Others are
probably busy with it being summer. Those of us in the upper midwest
haven't had a "normal" summer yet this year which is just fine by me.
Bring on the drought, bring on more cold summers!

Hi Mac,

'tis the nature of things. Participation has been falling from the
peak of 1999-2001, down by about 6dB on average, but 10dB for July (if
posting volume were power, mostly dissipated heat; double that if you
think of postings as lost potential).

The posting count follows the classic battleship curve of emerging
then declining fads, fashion, schools of thought, what-have-you social
trends. We are now as engaged as we were in 1995. Consult:
http://groups.google.com/group/rec.radio.amateur.antenna/about?hl=en

I would not speculate or offer that counts indicate quality, however.

Dear Richard and Group: Ah so!

Since I have taken to automating the purging of notes from authors-of-noise, it occurred to me that I might have turned up the squelch too high. I am relieved to know that is probably not the case.

In the matter of antennas: my esteemed colleague AB8T's EM class' antenna project was a great success. Students designed UHF TV antennas (Channels 14-51) using EZNEC5+, constructed the antennas, and then had their performance compared to expected. It was an opportunity for students to learn-by-doing in several areas. As readers on this group know well, antennas involve several areas of science and engineering. The one important area not covered because it was thought too far from EM, was the issue of survivability in the presence of wind/ice loads.

Hi Mac,

It sounds like you will survive this fading battleship curve by having
secured your own life boat with these class projects - congratulations
to AB8T.

Myself, I find more interesting "antenna" applications being designed
at the nanoscale in a remarkable field called Surface Plasmon
Resonance.

Source record: 14120

Hi

I am trying to build a broadband UNUN 9:1 from 1.8 mhz to 30mhz. I
have had no luck.

The first one the that I built, I used #67 material trifila wound 8
or nine turns. This one works
from 80 through 15 meters.

I also tried a Quadrifilar winding on a #67 and #61 core as multi
impedance transformer, still
narrow band with bad or high VSWR from 10mhz to 30mhz.

I tried another one with #61 material and did not have much success.

I then tried a auto transformer type primary 9 turns secondary 44
turns using a Amidon 61 core.
This produced a nice low frequency UNUN .5 mhz to 10 mhz.

The question is simply how do I build a broadband UNUN or
Autotransformer from 1.8mhz to 30mhz and what core do I use? I am
coming to the conclusion that these auto transformers or high
impedance UNUN's are narrow band devices?

I am playing around with a terminated T2FD type antenna trying
different impedances, 450,600,800 and 1000 ohms termination resistors.

Bob

Of course, but it's "Climate Change", that way no matter what happens it the fault of humanity.

On a similar note, has anyone noticed how the sun's output has a lot to do with the climate? And that it sort of tracks what's going on? Ok, tracks quite well.

Type 43 or a 70-series ferrite is a better choice for that frequency range, and 70 series is probably better for the relatively high impedances you're dealing with. And as Richard said, you might have to do the transformation in more than one step.

Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Something else that tracks quite well is the size
of the ice caps at the North Poles of both Earth
and Mars proving, beyond a doubt, that there must
be intelligent life on Mars generating emissions
that effect Climate Change, just like here. :-)

Question is: Where are you going to find an antenna that
exhibits a feedpoint impedance of 450+j0 ohms from 1.8 MHz
to 30 MHz? Here is a Z0=450 ohm ladder-line-fed all-HF-band
antenna that exhibits a feedpoint impedance at my QTH
between 40+j0 and 87+j0 ohms on all HF bands and needs
a 1:1 balun with no conventional tuner.

http://www.w5dxp.com/notuner.htm

Would you mind describing the antenna system that requires
the specified balun?

> The question is simply how do I build a broadband UNUN or
> Autotransformer from 1.8mhz to 30mhz and what core do I use?

It's extremely difficult to build a balun that functions
properly over a 16:1 frequency range. It is relatively
easy to build one that functions properly over a 4:1
frequency range. I would suggest building two baluns and
switching between them, one for 160m-40m and the other
for 30m-10m.

You don't state what shape the core is. Have you tired a binocular core? I
wound up a 9:1 on a 43 binocular core and see under 1.5:1 from 500KHz to
30MHz on an Agilent network analyzer.

How critical was the aiming of the antenna? I'm asking because if I
build one, many wavelengths long, it probably won't be easy to move the
poles.

The bigger it is, the more critical. Longest rhombics have the highest gain
and, by necessity, the narrowest beamwidths.

Beamwidth is usually specified as the angle between the two 3 dB points on
the left and right sides of the beam. Most designs either specify the
beamwidth or show you a polar plot from which you can arrive at the
beamwidth by inspection.

It is not inconceivable to make a rhombic structure that pivoted about a
single point at the feed and was supported at the terminated end. An
insulating structure would be needed but if you were to confine it to UHF, a
five-wavelength rhombic would be about 15 feet long. Awkward but not
imposssible; we already do it (or close to it) with some of the larger quad
antennas

Thanks for all the information.

The 9:1 works with 8 turns trifilar, on the FT240-67 from 80 through
to 10 meters. Its poor on 160 meters.

All the cores are FT 240 size from Amidon or Bytemark. I can get the
transformers to work but only over a narrow frequency range for the
higher impedance ratios.

I notice that the Sevick UNUN thats sold by Bytemark, a 18:1 ratio
is narrow band and wont cover 1.8mhz to 30 mhz. Anyhow i dont have
the magic recipe yet but I will keep experimenting.

Bob

Message-ID: <w6adnQwYeKtxVujXnZ2dnUVZ_o6dnZ2d@giganews.com>
Source record: 14134

I'm thinking about hanging a dipole from a roof gable to a tree. Of course the feed line connects
to the dipole in the center which presents a problem: If I drop the feed line straight down it will
end up in the middle of the yard where people walk and the grass is mowed.

Is it possible to run a coax feed line back to the house along one leg of the dipole, perhaps
suspended a foot or so below it?

1023. Counterpoise for an end-fed wire antenna

Newsgroup: rec.radio.amateur.antenna

Message-ID: <NvWdnVlLypTfUOjXnZ2dnUVZ_gqdnZ2d@giganews.com>
Source record: 14135

I'm confused about the requirements for a counterpoise for an end-fed wire antenna. I understand
that it's needed, but I don't understand what the requirements are.

Can a ground stake at the base of the feed point serve as a counterpoise, or does it need to be
another wire running under the ground below the antenna?

If a wire is required, how long does the counterpoise have to be?

Would it be better to use insulated or uninsulated wire for a buried counterpoise?

If you get 100 replies, you'll probably get 110 different answers to that.

> Can a ground stake at the base of the feed point serve as a counterpoise, or does it need to be
> another wire running under the ground below the antenna?

No, it makes a good DC ground for lightening protection. A counterpoise can be
run almost anywhere, and the more the better.

> If a wire is required, how long does the counterpoise have to be?

.28 wavelength is something I have read, while most people use 1/4 wavelength,
or an electrical equivalent (shorter due to velocity factor).

> Would it be better to use insulated or uninsulated wire for a buried counterpoise?

Uninsulated.

Not that some antennas don't need a counterpoise, for example a 5/8th wave
antenna or an end fed zepp which uses no or a very short counterpoise.

A friend of mine has a commercial antenna, which consists of a matching
network, a trap and around 40 feet of wire. It covers 10,20 and 40 meters
with no counterpoise. The matching network can only handle 25 watts,

My speculation is that it's sort of a 5/8th wave type antenna with
loading coils to eletrically lengthen it.

It could also be a 50 ohm 25 watt resistor with a long tail on the "hot" end,
but I really doubt it.

Geoff.

Hi OM,

Sure, it is possible. Many do and live comfortably with the odd
characteristics that follow from it; and it probably doesn't alter
their expectations of performance.

This, of course, suggests that you have left off a list of unexpressed
presumptions like wanting directionality, low SWR, no RF hot chassis,
and so on that follow as problems from such an arrangement.

One solution (although it may be difficult to manage for multi-band),
is an horizontal sleeve dipole.

Hi OM,

What are YOUR requirements? (What bands, how long is it?)

>Can a ground stake at the base of the feed point serve as a counterpoise, or does it need to be
>another wire running under the ground below the antenna?

Both, and more wire(s).

>If a wire is required, how long does the counterpoise have to be?

For single band operation? (You aren't very clear about this.) The
deeper into the ground (and deeper than 6 inches doesn't count for
much), the less resonant it will become. Make it as long as your wire
overhead - maybe less.

>Would it be better to use insulated or uninsulated wire for a buried counterpoise?

Doesn't matter.

With regard to whether you need a counterpoise or not. If your
antenna has two wires at the open end (feed point) then they both must
be connected to the transmitter where there is also an additional
provision for a ground connection (a must in all cases as the chassis
is floating).If the radiator has only one termination then only one
transmission wire can be connected to it leaving the other wire to be
connected to a ground system which in effect balances your radiator
with a load that does not radiate unless it is the form of a
counterpoise. The effectiveness of your ground system can be measured
by its effectiveness in supplying a resistive feed impedance somewhat
near 30 ohms (above 20 ohms) or so where your transmitter does not
encounter any problems, a counterpoise will present a higher
impedance. An end fed antenna cannot be of a fractional wavelength and
thus the ground field or counterpoise is required to be added to
provide an impedance that can be fed by the transmitter without a
problem so you can enjoy useage of your antenna

An end fed wire antenna should be very close to a half wave in length
for the intended frequency. If coax fed, the objective is to make the
antenna look as balanced as possible by insuring that the current in
the counterpoise and the radiating element are very nearly equal. A
half wave end fed is a high voltage low current antenna, and
everything around the antenna will affect its impedance and balance,
obviously the counterpoise will have a large effect.

If the end fed antenna (half wave) is not in the clear, then the
counterpoise is cut-and-try. If in the clear, antenna modelling will
provide useful results, see W8JI web pages. A counterpoise is needed,
but without knowing your exact situation, cut-and-try is your best
bet.

Hello,

As you might know, the current that goes into the end-fed antenna
equals the current that goes into the counterpoise.

The requirement for a good, efficient counterpoise is that it should
not dissipate the RF power and that (preference) the impedance is far
below the feed point impedance of the end-fed antenna.

The requirement last mentioned is for assuring that you can feed your
antenna with an unbalanced feeder (coaxial cable). It also helps to
avoid that when you touch a coaxial connector while transmitting, you
don't burn your fingers.

Half or full wave resonant antennas have high input impedance (kOhm
range), hence requirements for counterpoise are easy to meet. It is
easy to create a counterpoise impedance of several hundreds Ohms.

For a quarter wave (or shorter antenna), the resonant impedance is in
the 30 Ohms range or below (for short antennas). In that case it may
be very difficult to get counterpoise impedance far below 30 Ohms.

As Geoffrey mentioned, with 100 replies, you will have 100 different
answers. There are many ways to make a counterpoise; all have their
advantages (and disadvantages).

Generally spoken, the more metal the better. However at a certain
point, doubling the amount/length of metal will not give significant
increase. When you add more metal and the antenna impedance at
resonance doesn't change, adding more metal is not necessary.

In my opinion, many short wires are better then one long wire. When
you have good ground conductivity, driving rods deep into the ground
is not necessary (skin depth issue). In case of single frequency band

operation, you might consider 2 or 3 elevated quarter wave resonating counterpoise wires.

I know this is not a direct answer to your question, but I hope it will bring you closer to an answer.

Best regards,

I think code calls for #6 solid Copper or Aluminum for lightning protection.
Consider the 50 ft as part of the antenna though. Rather than even trying
to have an RF "ground" try to make a counterpoise instead. Read up on the
difference between RF ground, lightning ground, and electrical ground. You
don't say what kind of antenna.

I regard a radiator with a counterpoise as being center fed of a given impedance to connect to regardles whether the counterpoise is above ground or not. If a radiator is of a closed cuircuit form it may be fed at any point in physical terms. Other peoples definitions may vary. The poster I understood to be at the position of the end of a transmission line with two wires in hand and wanted advice from that point to procede. If his advisers are going to quibble then he needs to go elsewhere for advise or settle for a poll.

All these questions depend on your particular situation. In a typical antenna installation you would first seek to follow the instructions for that antenna. Especially if you don't understand the physics involved. You will probably already have some sort of ground through the power supply. Any better ground than that must actually be better to whatever energy you are trying to "ground".

Someone mentioned RF in the shack and being bit from the chassis or connector shell. The best way to avoid that is for the energy at the coax connector to see 50 ohms, and for the radiating portion of the antenna to be well out of the shack. In that case, you don't need an RF ground on the radio.

A ground stake at the feed point along with a remote tuner should be sufficient if you have really low resistance soil. You will probably benefit by adding a counterpoise and you will probably never have a perfect ground. It is better to have uninsulated wire because it will conduct into the ground. Some think insulated is better because it will last longer for a little expense in performance.

A remote tuner (or matched antenna) at the feed point, will keep the RF to the transmission line and prevent high voltages on the line and keep losses to the minimum.

Interesting question.
The poster is in an attic which suggests he will need a very long wire
to get to a "ground." Presumably the chassis of his radio is
connected to a "ground" at a service pole via the power plug.
The antenna I assume is floating above "ground" via a inter connecting
capacitor of a low breakdown voltage to the chassis. So one has to ask
what an added "ground" wire is going to do for you and what
disadvantages with respect to protections it is it putting in place?

This is a simplified way of looking at things. It only works if he is to use a horizontal loop, but doesn't address matching the antenna to the line and in the case of "two pieces of wire", you won't have a clue where the electrical "center" is. One of the original posts was about a dipole where the coax would have to follow one of the legs because it would hang down where it shouldn't be. That makes the feed point NOT in the center and prone to common mode currents on the line.

It took me a couple of posts to realize the Poster has made multiple posts questioning different aspects of his problem and we get the whole scenario from chasing down all his threads.

It looks to me that his real estate won't allow a balanced antenna anyway, so he will have to deal with the issues of an unbalanced radiator anyway. I first thought of an Inverted L as an optimal antenna for his situation, with remote matching for multi-band operation to keep RF out of the shack. An elevated horizontal loop or off center fed dipole with ladder line to a tuner at the entrance of the shack would also be an answer to the problem. A multi-band vertical would be a good choice for 30-10 meters. Although they work for 40 and 80, the pattern is not as good as a horizontal antenna for exploiting the shorter skip.

> around with additions supplied by man

Man has no effect upon the weather? Fine, show me the mechanism by which the retention of heat in the atmosphere is not affect by the percentage of greenhouse gases and water vapor. We would not exist without the effect, so discarding the effect is impossible.

So now, WHY is the increased percentage being negated. To show a heat retention effect is not difficult, middle school students do it all the time.

But what we get is political statements. A political statement declaring that the greenhouse effect doesn't exist is just as valid as noting that since the present administration has been in office, there haven't been any hurricanes. So therefore, there are less hurricanes when Democrats are in office. Of course that's a stupid statement. But both statements are. non-sequitar maximus.

BTW, mining the available data to produce one anomalous result is just as bogus. The creationists and lunar landing hoaxers have been doing that for years. You have to produce the theory first, then find supporting or refuting facts. The deniers don't produce an alternate theory - they only try to disprove.

I could put a surface wire counterpoise in the crawl space under my office where the radio is
located. If I did that, there would be only about a 5 or 6 foot run to the center point of the
counterpoise.

Assuming the counterpoise wires are laying on the dirt floor of the crawl space, how many wires
would I need, and how long do they need to be. I want to be able to work 6 through 40 meters.

If I install a wire counterpoise like this, is there any problem also connecting the earth ground
connection to the central ground bar in my office?

The attic antenna is an Alpha Delta DX-EE.

>
> How did it work out for ya?

The installation was behind the backrest of the bike, I made an aluminum plate that held the antenna and the radio body. the wires to the head routed up under the seat and tank. The head was installed off the handlebar, right in the middle.

Cosmetically, it's about a 9, performance is pretty good also. I can hear well with a pair of "skull candy" headphones, which are a little like earbuds, but rest on the ear instead of being pushed into them.

I do have to work on one problem. The head is waterproof, but the body is only water resistant. A couple of rainstorms have allowed a bit of water to get into the head/body connection. I have to add a little cover over that. I might try to find some of that goo they put around tail lamps to seal out water. Overall, I've been pleased. No dead battery yet, although I try to avoid the full 50 watt output of the unit.

You are correct. I should NOT have given a simplified response to a simple question.
Your technical answer is a much better response tho I suppose I could have made mine as technical so that he would not ask questions any more! Good point about common mode. That should screw him up as well as other things that you inserted with respect to how does one connect to an antenna. We could ask him I suppose how many wires he intends to connect to his intended antenna feed point, and if it is not two then question how he intends to measure the impedance for matching purposes. Yup, I could have done a better job.

The last time I checked the minimum wire size for a ground intended to protect from lightning is #6.

50 feet of any wire will not work as an RF ground for anything other than a quarter wave at 50 feet!

Your next question is about driving another ground rod: If you do, the second ground must be tied to the first with a minimum of #6 wire or you set up a dangerous ground loop.

That's a good article, but it is focused on grounding for lightning protection. I am interested in
that, but I am also interested in having an effective RF ground.

I've been able to get a total of 16 feet of ground rod down in the form of 4 four-foot rods, but I
have a 50 foot run from my office to the ground rods, and I'm concerned about RF impedance in that
connection.

OK. Would it work to construct a radial counterpoise in the crawl space under my office? It would
only be about a 5 foot run to the center of the counterpoise.

If I lay wires on the dirt floor of the crawl space, how many radials would be required and what
would the length be to handle 6-40 meters?

All this discussion of "counterpoise" should be centered around Single
Frequency Antenna Systems Design, and is NOT relative to multi-Band, or
Wider than 10% of Frequency, Bandwidth, End Feed Antenna Designs. These
latter Antenna Systems are not using a Counterpoise, as such, but REQUIRE
a LOW Impedance BroadBand RF Ground, which in most cases needs to be
built, on site, and engineered to provide that Low Impedance, Wide Band
RF Characteristics for the specific Radio System. Having spent a career
designing, installing, and operating LF/MF/HF Communications Stations,
all over the world, it isn't a trivial undertaking, should one actually
want the best Antenna System, possible, for any one location. There are
MANY factors to consider, with Ground Conductivity, Water Depth, changes
of these during the passing seasons, and Frequencies and Bands chosen
for communication links. In many cases an End Feed Vertical, just isn't
the best Antenna System for the location. In other cases, they can be
designed for really good efficiency and great propagation. On of the
best Systems I ever installed was a 70' insolated Tower, with a SEA-330
AutoTuner tied to the center of a 100 Sq Ft Galvinized Screen built in
the center of a One Sq. Mile Salt Marsh, that flooded every 12 hours on

High Tide. Rf Impedance was below 5 Ohms from 200 Khz, clear up thru 22 Mhz.

The two are pretty much Mutually Exclusive. What makes for Good
Lightning Protection, really doesn't have ANYTHING to do with RF
Grounding, especially if your using an End Feed Vertical, for an
Antenna. Lightning Protection is a Ground Rod that meets NEC.
Low Impedance RF Grounding System design is a Science and Art all in
itself.

Yup, I could have done a better job.>

Art,

See the original post asking: "How to route feedline from dipole".
If he were to let his coax hang straight down from the feed point, there would be no discussion. In asking about dressing the coax along one of the dipole legs, Common Mode currents are induced on the outside of the shield and there is no longer a simple discussion. His further questions arise out of trying to deal with that problem of not being able to let his coax hang where it wants to.

Also, one leg of his dipole will be over the roof and the other in the clear, so one leg will be detuned to throw more trouble into the mix.

To get him on the air quickly, a tuner is desirable. If he has that, he might as well make a multi-band antenna where his feed point location is elsewhere. I think he got that because then he asked about counterpoise and ground, which is the next step in the evolution of that type of system.

This is a specific technical problem.

1059. Expansion issues with PVC

Newsgroup: rec.radio.amateur.antenna
Date: 2009-08-03 21:00:42 UTC
From: Dave D <xray66@earthlink.net>
Message-ID: <4b829fc8-b2ca-4152-b667-099eb8c554df@v23g2000pro.googlegroups.com>
Source record: 14071

I've used PVC for enclosures in the past and didn't seem to have any trouble. But I noticed that on a couple projects we had a couple things that started to bend from thermal expansion. The sunny side of the free standing vertical piece heats more than the shadow side, and the differing expansion rate creates a bend. Even for a 5' piece, it seemed fairly extreme. But then other times this hasn't happened. We were using the special furniture grade PVC in 1" size. Anybody had any experience with this or come up with any solutions? Notice any difference between PVC types or anything?

Thanks for any help,

Atta boy Bruce!
A ground plane or counterpoise is part and parcel of a antenna all of
which does not necessarily radiate and it is not of the same potential
of the true ground that should be at the lowest potential of them all.
It is for this reason the transmitter chassis is grounded and
separated from the radiator system which has it's own closed circuit

and where the potential is above that of true ground. In this way your transmitting circuit does not have a ground loop which is the last thing that you want.
Lightning tries to get to the true ground by the shortest route and the requirement is for you to not be part of it's route, even if your radio has to be the sacrificial lamb if you haven't pulled the plug.

i don't know where you get your radios, but in all of them here the coax
connector is connected to the transmitter chassis which also has a lug for
going to the safety ground.

there ain't no such thing as 'true ground', tis all relative.

ONLY if the counterpoise is connected to the same location where the
'radiating' wire leaves the coax. if you run a piece of coax out the window
and connect just the center conductor to your end-fed antenna then connect
the 'counterpoise' to the radio ground lug as is commonly done, the current
in the counterpoise may be MUCH different than that going into the wire.

First you have to determine if all samples are equal and whether your
dealing with open or closed pore or different manufacturers Then
compare with respect to environment. There is no magic solution

You're right, Art. The last Global Warming cycle
peaked about 8000 years ago and ever since, the
average temperature has been drifting down toward
the next ice age. That is obvious to anyone who can
read a graph.

Therefore, get rid of all the water and CO2? It
appears from the following graph that C02 density
is a lagging indicator introducing the next ice age.
25000 years from now, those greenhouse gases will
come in really handy.

The bigger the better, but number 6 solid is kind of a stantard with antenna suppliers that furnish it. I use whatever I have that is high current carrying. #4 or #6 or bigger. Grounding is an art of it's own so you should study it as any other aspect of electronics. The experts run all the ground absorbers to a common buss bar and and the ground collectors to that bar. Make a study of this as there is no easy answer.......Rollie

By golly, I believe you are correct! I thought that was a bad
practice! Are all electronics at the same potential in the U.S. as
its container? So with a ground connection at the electrical supply
point and a provided connection for another generated "ground", is
that not an invitation for ground loops?

>
> >Lightning tries to get to the true ground by the shortest route and

H'mm, the ground point with the lowest potential relative to other
ground potentials in the same system is the "true" ground of the
system. Now can you tell me which "ground" is protected and from
what? And RF ground; is that protected from lightning? Lightning is
multi frequency oriented so it would appear to me it would gyrate
towards a radiator.
What about just one wire to the antenna and let the earth be the
return line to close the circuit! Seems like the definitions have gone
awry without involvement of a chassis ground
but then it is you that is electrically educated and the better judge.

Hello Dave,

I supposed the counterpoise to be connected at same location as where
the antenna connects to the coaxial cable (so the cable is used as
feeder only). When you connect the counterpoise at the tuner, the
cable will be part of the radiating structure and, as you mentioned,
everything changes.

Best regards,

Wim

1072. Quad multiband

Dear OM, I would like to build a Cubical Quad multiband and I've found the site of EI7BA
http://www.iol.ie/~bravo/Cubical%20Quad.htm, I'd be interested in building up something like that but with 3el. I was thinking about having the director and reflector opened at pyramid-shape like the EI7BA project but the radiator at normal crossing like the fixed spacing in the common multiband version.
Do you have any projects or tips? I'm a newbe in building antennas.

That's about a quarter wave at 5MHz. It sure isn't an effective
ground.You'd need a tuner on the ground wire as well.

Hmmm, did you get that I was inferring that from saying we would not exist without the Greenhouse effect? I'm not trying to eliminate everyone.

> It
> appears from the following graph that C02 density
> is a lagging indicator introducing the next ice age.
> 25000 years from now, those greenhouse gases will
> come in really handy.

Aren't you arguing both sides of the issue now, Cecil? If Greenhouse induced warming is bogus, then those gases won't come in handy, will they?

Given that climate change is going to happen regardless of human input, I'd make a guess that at the turning point of a heating cycle, the oceanic currents will shift, due to loss of ice blockage at the poles. Then, the change is agumented/mitigated by solar output. Also augumenting/repressing is effects such as atmospheric dust and sulfur dioxide content, and yes, the amount of greenhouse gases in the atmosphere.

All this gives rise to varying average temperatures, and depending on the timing, can make a greater or lesser cooling or heating effect.

Now given that there is a lot of natural variability, does it follow that humans should pay no mind to their own additions to the load?

I believe that we need to find out the effect, and the extent of the effect.

Taking the idea of the greenhouse gases coming in handy, I can envision being at one of those sharp drops in Temperature, and using gases to moderate the temperature. There is a lot of Methane in the form of clathrate hydrates, that might just spell the survival of humanity. Or maybe not. Maybe we should know what it will do.

> http://upload.wikimedia.org/wikipedia/commons/c/c2/Vostok-ice-core-petit.png

Looks to me like a pretty fair correlation, Cecil. Now what I am interested in is the event that occurred at those peaks, and also the valleys. It's fairly sharp. I don't doubt that as things rapidly cooled,

that there was a reduction in CO2 in the atmosphere. What was the cause?
It's a great graph for speculation. Interestingly regular.

Gathering from your other posts, you are in a difficult situation. RF grounding from a non ground floor or basement location is an issue. The problem is proportional to the frequency and wavelength, which is to say that at 10 meters, your RF ground won't.

Is there any possibility of putting in a balanced antenna? Or one of the so called no-ground verticals? All antenna setups are a compromise of one sort or another. Your setup will be a little bit more of a compromise.

This isn't to say there is no solution. There is always a solution of some sort.

Okay, then what is the mitigating mechanism for mankind to not have an effect? We are increasing the percentage of greenhous gases. Why does it not have an effect?

> I strongly suspect
> the primary source of energy in our solar system
> is the cause. Now what could that be?

It would take an absolute idiot to not think that the sun was the major influence on the temperature of the earth. But I don't think that it follows that man has no effect on the system.

A prime example is the planet Mercury. It catches quite a bit more solar radiation than we do on earth. But the parts not catching the solar radiation aren't warm at all. And Venus, which catches more than we do, has temperatures that are much higher than would otherwise be expected, and these temps are not in areas directly exposed by the sun.

Do you have anything attached to the PVC? if you have a wire running vertically, and especially if it is attached tightly, that might account for a bend.

Hello,

Just a typical non-technical sw listener, and frankly now next to nothing re antennas.
But do like picking up maritime and mil stuff.

Was thinking of trying out a new software Inmarsat program for receiving and decoding Inmarsat msg's.

Apparently the freq. used is around 2 GHz
My NRD 545 wiuth the converter gets up there, I think.

They mention that you need a parabolic dish antenna, and I think it was an L type downfeed feed.

Think a Discone antenna and reg. coax would pick up "anything", or not worth the time to even try ?

Thanks,
Bob

The Global-Warming/Ice-Age cycle has been primary and we
are 8000 years into the next ice age. If man has any effect
at all, it will be to delay the onslaught of the next ice age.
Indeed, this ice age cycle seems to be somewhat delayed
compared to the previous ones.

Seems that you are asking for proof that man doesn't have
any effect. That's a lot like asking for proof that God
doesn't exist. The onus of proof is upon those who assert
the positive. Nobody has proven that man is or can be the
anywhere near the primary cause of global warming. The
ice-core temperatures prove that the most severe global
warming(s) occurred before man ever existed.

> But I don't think that it
> follows that man has no effect on the system.

I think you would agree that plants have much more of an
effect than man? Plants love CO2 and produce O2. There
was a time in the past when the oxygen level was double
what it is today and dragonflies had a wingspan equal to
my armspan. Believing that man has a drastic effect on the
present global temperatures is akin to believing that the
earth is the center of the universe, i.e. delusions of
grandeur, e.g. Al Gore.

>> Now what could that be?
>

Basically, there are two sets of MIL SAT setups... there is the UHF
Military stuff between 200 - 400 Mhz, and then there is the true Marine
stuff in the Shf bands. YOu can hear some of the Tactical UHF stuff with
your discone, but most of that is now encrypted. The Shf stuff would
require a knowledge of which SATS, and their locations in the sky
relative to your house, and at least a one meter dish for solid
reception, as well as an understanding of Modulation schemes used,
decoder hardware, Frequency, and Polarity. This would not be for the
fainthearted.....

You probably won't have enough SNR without a gain antenna. Doesn't need to be huge, but you do need more gain than you get from an omni.

Inmarsat operates in C (3.6 GHz down, 6.4GHz up) and L (1.525-1.559 GHz down, 1.626-1.661 GHz up) band, not S band. What you heard about was using a small parabola and an L-band feed for the downlink (at 1.5GHz)

Inmarsat Mini-M uses a very small antenna, and in fact, has the ability to talk to a satphone with a small antenna (briefcase sized)

> connection.

I ran attic mounted antennas for a period time and here is my
experience. First, don't bother running any ground to the antenna,
especially at 50 feet long. It will act more like a radiating element
than a ground, then you will get to meet Mr. RFI as you will discover
all types items your RF can affect. Since your antennas are in the
attic, static and lightning should not be an issue, unless you or a
close neighbor takes a direct hit.

I keep everything disconnected unless I am operating, it is the only
way I know of to keep lightning from destroying your station. If you
or your neighbor takes a direct hit, there is not much you can do to
prevent damage, unless you have everything disconnected, AC/Ground/
Antennas/Control lines/etc.

Second, your four foot ground rods are about useless for both RF and
DC ground. Minimal is eight feet. My current station has 7 eight foot
ground rods, spaced no more than eight feet apart, and all grounds are
tied together, including the panel box ground. This is done to make
sure all grounds are at the same potential.

You did not describe your station so the information someone can
provide is limited. In my case, my station was on the second floor,
so instead of having a ground, I used a tunable counterpoise system as

my RF ground. MFJ makes the tune boxes, and Ten-Tec may still sell them in kit from too. I used the one from Ten-Tec, it worked well at my location, but it still was a compromise, when compared to having a true ground system and outside antennas.

yes, it is. that is why your 'shack' ground has to be connected to the
service entrance ground.

>

>ground potentials in the same system is the "true" ground of the
>system.

you have to define the 'system'. but there is always the possibility that
someone outside the 'system' can reach in and measure your 'ground '
connection relative to something else and measure a potential. potential is
what is relative, hook a 12v battery to a meter and set it on a table,
connect another 12v battery between a ground rod and one terminal of the
first battery... does the meter reading change? what is the potential of
the positive terminal of the battery? if you were sitting on the table and
couldn't reach the ground rod or 2nd battery terminals could you tell what
the voltage of the 2nd battery was?

>Now can you tell me which "ground" is protected and from
>what?

'ground' is not protected from anything. 'ground' is a convenient point to
connect everything and to make measurements from.

> And RF ground; is that protected from lightning?

there is no such thing as an 'rf ground'. there is at best a low impedance path for return currents to get back to the feedpoint... if that happens to be through the earth (note for you, earth means dirt, not earth as in electrical ground that we call it in the states) then we may want to call it 'ground' but it really isn't.

now, why do i say there is no such thing as an rf ground? consider what happens around a 10m 1/4 wave vertical mounted on the ground connected to the center conductor of the coax, with a single ground rod as the connection for the shield of the coax. The current going into the 1/4 wave vertical and the current coming out of the ground rod have to be equal at the coax connection... so, current flows up the vertical, back through the ground, up the ground rod and back to the coax... very simple... until you take your rf voltmeter and connect it to the ground rod and stick the other probe in the ground some distance from the rod, lets say about 1/4 wave away (more or less, propagation velocity through the ground is slower so it would be physically less than 1/4 wave in free space, etc, etc). what voltage do you read on your meter?? it is difficult to calculate because of all the interfaces and bulk conductivities, the sizes of the ground rod and probe, etc... but suffice it to say, it ain't zero. why not, aren't both probes connected to 'ground'?? well, yes, and no. because there is current flowing through the earth trying to get back to that coax connection there has to be a voltage difference. current in earth * resistivity of earth = voltage between points on the earth, give or take a few units. now lets say we add a radial wire to connect the ground rod at the feed point of the vertical to the probe where you measure the voltage of the earth... does the voltage go away? after all you just shorted out your voltmeter didn't you?? but no! there is still voltage! why you ask?? well, even though you have made a lower impedance path there is still current on the wire, and since the wire has inductance and capacitance the propagation time is not zero, so there is still a voltage difference causing that current to flow along the radial wire... why is it necessary to insulate the ends of raised radials if they are a 'ground' plane under a vertical antenna?

lightning 'ground' is even worse because the currents are bigger... consider a 100ka bolt with a rise time of 1usec hitting the ground and spreading out at about .3c (approximately what i measured in one experiment for a buried radial wire)... the potential difference between points just a few feet apart can be huge, that is a common cause of lightning deaths, current hits tree, goes through ground, up one leg, down the other, or up one leg and out an arm that is closer to something conductive away from the tree... like a golf club. the key with designing lightning 'ground' systems is to realize that this potential exists and make sure you can handle it. the 'single point ground' is the classic way because it makes the distance zero which takes the rise time and propagation speed out of the equation. unfortunately that is not always possible, so that is where other methods are needed to keep voltages across protected equipment equalized.

>Lightning is multi frequency oriented so it would appear to me it would
>gyrate

>towards a radiator.

i have never known lightning to gyrate. it takes all sorts of convoluted paths, but none that i would call gyrating.

>What about just one wire to the antenna and let the earth be the
>return line to close the circuit!

certainly, and many have done that, and some have gotten burned. consider this case... sit on your table with the 12v battery again, but instead of the meter hook up a transmitter to it. assume there is one so-239 output jack mounted on the radio's metal case and no other connections, just 12v in, rf out. run a wire straight out from the so-239 center conductor then touch the radio's metal case... what happens? if the power is high enough you get burned... why? you are touching the radio case, isn't that 'ground'? you aren't touching the earth? so what is happening??? well, you are now part of the return path for current that has to find a way back to the chassis side of the so-239, and since you are likely much larger than the case of the radio you make a more efficient collector.

change the setup, now run a wire from the case of the radio to the ground rod where the 2nd battery used to be connected... now you have another path for current to get back to the chassis side of the connector, from the 'earth' through the ground rod up the wire and to the radio... now touch the case and what happens? well, if the earth to radio circuit is lower impedance than your body to radio, more current flows on that side and you don't get burned... not good enough? still getting burned??? get one of those counterpoise resonator thingies... they are really just a small match box for a long wire... run the wire around the floor and tune it up. why does it work better? it provides a lower impedance path for collecting up that return current and getting it back to the radio. no magic, it is just providing the return current instead of letting your body collect it.

> Seems like the definitions have gone awry without involvement of a chassis
> ground

ah, chassis ground, yet another type of ground.

>but then it is you that is electrically educated and the better judge.

one of the few things you have said that i agree with

Document it. HF Motorcycle is rare enough that any effort would be of great interest. You'll be wanting to maximize your "ground" area. The HD has a lot of iron as bikes go, so you'll be starting out wit a best case there. Of course on a bike, there isn't a huge amount of that. Ignition noise will be an issue also, but with some effort, all this can be overcome.

Your screwdriver would be a good way to go.

I hope you do it, because it would be way cool.

This is a balanced antenna and if the antenna is stretched out in an area
where there is no metal it should do it's best. You probably won't benefit
from a counterpoise at all. In fact, any RFI you might encounter will have
to be specifically addressed because of the antenna is within the living
quarters. Your antenna will be too close to the ground and partly shielded
by roofing materials as it is for optimal performance, but we do what we can
just to get on the air when there is no good solution. Having said that, You

should be able to load up with an outboard tuner and make some contacts.

The electrical ground is Neutral at the entrance so that any wires shorting to the boxes or metal cabinets will pull the breaker and so that none of the cabinets can have AC potential on them. The lightning ground should be there at the entrance because that is the common tie point of all grounds, and any lightning currents flowing on the ground wires throughout the house will induce massive voltages into the house wiring. If you have multiple ground rods, they should tie together with heavy cable to the panel before all else. There is a problem with a good RF ground at the antenna, because lightning strikes to the power pole or house will want to flow through your station to the good ground in addition to the panel ground. So it is a good Idea to at least bring the coax and all wires to the electrical entrance for protection before entering the house and preferable to site the tower outside the electrical box and bond all grounds with heavy gauge conductors.

The man is putting a dipole in the attic, so this talk about ground is a moot point.

The "balanced" antenna is connected to an "unbalanced" system if the rig has AC power through any device or has a powered mike connection, or has a computer control line, or has a powered speaker, or has a ... and so on. It takes supreme effort to maintain "balance" but most are happy to ignore analysis and put a rubber stamp to it.

That an antenna is in a attic space is, no doubt, a cry that it is insulated from the sky. If that were all that was needed, every plastic covered wire in the air would be lightning proof. That is a superstition. If it were as effective as supposed, no one could use the antenna for its purpose.

The only bright point of there being so few reports of lightning strikes to attic antennas is that they present so little individual risk that low within a neighborhood of equally available targets - you could as easily use a closeline. Every home in a community over 30 years old has a vertical radiator penetrating the roof line, the plumbing system vent that dives solidly straight into ground. How often is a house struck there?

John,
Do a Google search (Hidaka+V-33+yagi+manual) on the correct spelling Hidaka.

Here is an excerpt from VK6IA web page:

The Triband Yagi - Hidaka VS-33 is the Japanese version of the Hy-Gain TH3.
It has proved to be a great performing antenna with good gain and a nice
front to rear/side ratio.

Hope for your sake the VS-33 and the V-33 are the same animal!
Maybe an email to him may prove fruitful.

Also found this.

Hi to all,
I am asking if anyone has the Specs for a VS33,Triband,beam for 10-15-20 M,I
have one and I can't find any info about it I have tried to contact
HIDAKA,in JA but no luck with them,I would like the trap info and element
lengths,as well,I have not pulled the traps apart to measure the coils
yet,so any thing would be a big help,Regards #TOM VK4HTM..

I am looking for the W9INN resonactor coil for the W9INN MBC-068
Broad-Bander. This is a full size 1/4 wave 80 vertical or L with 160
shortened to about 115 feet.

I lost the coil several years ago but wil be glad to buy a complete antenna
if necessary.

thanks es 73 Dave K4JRB

The idea behind the counterpoise was to provide an RF ground for the radio, not as a part of the
antenna.

I have a friend with an Alpha Delta DX-EE in his attic, and he has achieved DX CC -- contacts with
100 countries. I don't know if it is a one or two story house. I'm going over to look at his
installation his weekend.

As far as I know, we've never had a lightning strike. From a lightning perspective, we are fortune
to have a hill at least 4 times as high as the house immediately behind us. Pity the house on the
top of that hill.

Hi Bern,

No information, a manual that isn't helpful, aside from that, what
makes it so good?

In other words, why not build an antenna that suits your needs? As
far as that goes, what about the KGD antenna was appealing? There is
nothing particularly remarkable about gracing it with a term like QRP.

Ah, I'd never mind the counterpoise if you are using the balanced antenna. Just put up the antenna, run the coax or ladder line, get yourself a good station ground and some lightning protection. You are not likely to get struck directly, but could be the victim of a large static buildup. Polyphaser makes very good ones, and there is a simpler one that uses a spark gap, which also provides protection. Don't know the brand of that one. Disconnect the antenna and ground it when not in use.

I'd say with this setup, you could do DXCC. DXCC and other awards have been achieved on more modest setups than what you are looking at building. You won't be the loudest signal on the band, but there can only be one of those anyhow.

Now get to work! 8^)

Hello...
Richard, you are right ! This antenna isn't a special case. It is only a very short dipole with a capacitor which adapt the impedance of the antenna at the coaxial line. Nothing very new or even miraculous! (I do not believe in miracles ;o).
I just want to make a comparison between several types of antenna (including a miraculous o).
I do not therefore wish to innovate in the miracle, but simply to replicate some in order to compare them (without spend to many money ;o)

There is no need for the "radio" to have an RF ground.
If you are feeding the radio with 50 ohm coax that is matched in a 50 ohm
non-reactive load (ie tuner or dummy load) the RF will stay where it
belongs. The only concern for the balanced antenna, is lightning protection
and shock hazard from the power supply.
The best lightning protection depends on your specific situation so I will
leave you to read up on that.

I don't have DXCC but I do have a wall of cards from around the world. Many
of them were logged when I was mobile to and from work or school. It will
sharpen your skills to steal them from the big guns. I had a regular daily
lunch break sked with an Aussie from my truck in the parking lot.when the
sunspots were working. Conditions can even favor the well placed weak
station over the big guns. That is the sport of it all.

The combination of "very short" with capacitor does not lend itself to
a match.

Concur 100 percent, JB. I know that new guys love the high power and high gain antenna setups, but NTS will learn a lot on how to be a better operator with a modest setup such as he proposes.

>Here is the link you could find more info about it :
>http://www.qrpproject.de/UK/kg-dipole.htm

Hmmm. It looks to me as if this may be a sort of L-match.

The basic antenna is a dipole, with each arm being inductively loaded at its base with a coil wound from magnet wire. The inductive loading would allow the relatively short dipole (which would have a very low radiation resistance, and a high capacitive reactance) to resonate properly on the 40-meter frequency.

Even when resonated, and even with the relatively high losses in the coils, the antenna's feedpoint impedance would probably be on the low side. If I'm understanding the German manual correctly, it's on the order of 20 ohms.

It sounds to me as if the antenna uses an L-match arrangement to raise the feedpoint impedance. This would be done by:

- Lengthening the tuning rods at the end slightly (or adding a turn or two more to the coils than would be required for resonance). This would increase the resistive portion of the feedpoint impedance very slightly (trivially), and would add some inductive reactance in series with the resistance. With the correct adjustment, the feedpoint impedance would be equivalent to 50 ohms resistive, in parallel with some amount of reactance.

- Place a shunt capacitor directly across the feedpoint, with the capacitor's value chosen to have a capacitive reactance equal in magnitude (but opposite in sign) to the antenna's parallel reactance. The two reactances would add, resulting in a zero reactance, and thus a feedpoint impedance of 50 ohms resistive.

A similar matching arrangement is sometimes used with mobile HF antennas such as screwdrivers and bug-catchers.

"How critical was the aiming of the antenna?"
Depends on the number of wavelengths in a side at the frequency you are trying to receive.

Arnold B. Bailey in "TV and Other Receiving Antennas" gives data for a typical rhombic on page 528. He shows a beamwidth of about 30 fegrees with deep nulls on either side of the center lobe. Gain is 14.5 db over a dipole or less. The rhombic is comparable to the parabolic antenna Bailey shows on page 525.

Actually, for a dual band to one feed, you can probably just
interleave the elements of a 2m and 70cm beam on the same boom and
connect the driven elements in parallel.

http://www.arrowantennas.com/ look at the model 146/437... they have
plans on the site to build it yourself. While they have a filter box
available, I'm not sure you actually need it.

Hi Paul

"For what it is worth", I support Jim Lux's advice. A 70 cm Yagii wont couple much power from the transmitter when sending on 2.meters It would be easy to test the effect of shunting the 435 receiving Yagii with the 2 meter Yagii. You could even do that with EZNEC.
An antenna like Jim suggests would be easy to build on a broom stick to test the effects of the 'other antenna'.

The principal value of the Log Periodic is it's bandwidth. That is not significant when only two discrete frequencies are considered. A disadvantage of the Log Periodic is it's limited gain. I fail to see where the Log Periodic benefits the user when only two frequencies are being considered.

Mechanical and electrical precision.

A single frequency antenna must be tuned very carefully.
The LPDA is "self-adjusting" and easy to make.
And you may change frequency any time.

Hi W

I hadnt realized that Yagiis were so difficult to build and tune. Have you considered telling the AMSAT guys about how they can benefit from your advice? It seems that most of the AMSAT guys have been using the "Arrows" for LEO satellite work.

How much attenuation is a wood roof with asphalt shingles going to introduce? All of the duct work
in my house is in the crawl space, and the phone and cable TV lines are also in the crawl space. So
there is no metal other than the roofing nails, and there's nothing between the antenna and the sky
other than the roof decking and shingles. I don't expect them to add a lot of attenuation, but I
could be wrong.

/paul W3FIS

Hi Paul

AO-51 is a good HAM satellite. It is 146 up and 435 down.
If you do want to get some good experience designing Log Periodic
antennas, you might consider a Log Periodic V. The V configuration takes
advantage of a three to one frequency spread, where a center fed 1/2 wave
dipole becomes 3/4 wave at 3 times the frequency. The low frequencie
pattern is little effected by the "V". The high frequencies (3 times the
low frequencies) appreciate the bending to the V because that allows the
sidelobes to add toward the "front".

There will be a slight effect of the other wires. Nails? probably not measurable. The roof itself at HF is not attenuating much, it increases as the frequency goes up. The biggest issue of this sort of antenna is the height above ground, and the possibility of RF interference with things in the house.

then forget all the complications of log periodics and just make 2 simple
yagis on the same boom. that is the common method of constructing
directional satellite antennas. same boom too complicated, just make 2
separate ones and mount them on a cross arm a few feet apart.

Then you would be wasting 98% of the frequency coverage
of the log periodic. The unused antenna elements would
constitute almost the total cost of the antenna.

As a happy user of MFJ and Cushcraft products I think it is good. As I
recall, Cushcraft was bought as part of an antenna manufacturing
package that was mostly commercial antenna products. As such, it was
not as profitable as the other products and most felt it would be
eventually be shut down. It should thrive under the MFJ flag.

I only want to cover 144 and 420, nothing in between! Just for LEO
satellites, where the uplink is on 144 and the downlink is 420, or vis
versa.

/paul W3FIS

I have an ELK and it works on those frequencies out of the box without any tuning. The 5 element ELK has the same performance as Cushcraft 2/70 beam it replaced. The Cushcraft was essentially two separate 3 element Yagis (6 elements) with a splitter harness to feed the two.

You say you only want to work 2 specific frequencies, but for the Yagi you will have to make adjustments because most that are pre-tuned, are optimized for 146-148 on 2 meters. Also, very few hams are content to stay on one frequency. There is so much to do and experiment with. ELK actually performs as a beam from 144 Mhz multi-mode action to far flung NOAA WX stations at 162 Mhz. ELK works at both ends of 2 meters without tuning.

It is also lightweight, portable and takedown and assembly is quick and easy. The downside is that you need to use lockwashers on the elements and glue the tips or they will work loose in the wind. Mine has been up for 5 years and I added a bell crank/pulley and cord running to the base of the mast to change polarization.

The upper limit of gain for a Log-Periodic is about 10db. A 3 element Yagi is about 7db and a 5 element is about 9 db. You have to go to a long boom to exceed 10 db with a Yagi.

There have been several LPDA construction articles in QST over the years, and there are a few on the Internet too. One that looked interesting, used angle stock bolted together with Nylon hardware for the boom/feeder, and another that used parallel Copper tubes with the coax routed from the rear through one of the tubes for the front feed point. One real big plus is

that you can get Brass and Aluminum tubing and rod in numerous hobby shops and hardware stores stock sizes that are just too short for 1/2 wave on 2 meters.

Maybe 3' makes a big difference. I have always seen a difference between antennas in the attic or stretched out on the roof, and antennas even a few feed above the roof. I don't know if it was shingles or what. It would really be interesting to see what kind of shingles are transparent. I have seen antenna farms hidden behind fake gables.

Hello
Why you ask
Well I have owned a few MFJ products,and everyone of them failed,buy poor
parts and assembly.
Hence the MFJ stands for More F_cken Junk.
I have also herd horror stories about MFJ Buying Hygain,and the support for
Hygain products went right down the tubes.
With all my experience with MFJ products,I will pay the extra $$ and buy a
better product then they produce
Just my opinion about the company,sure there prices are cheap but there
price reflects the product
Howard

I've never "played" with it at HF, but I do know that the dielectric
constant of nearby materials affects antennas at VHF.

If MFJ's price to quality ratio was much
too low or much too high, they would go out of
business. Their success indicates that they hit
their target market and maybe even the bullseye.

MFJ thrives, and that is because they are serving a niche market.

MFJ designs tend to be good, the execution isn't always so good.

That being said, they make their stuff for Amateurs, they make stuff that I just wouldn't buy otherwise because it would be too expensive. That's that first point above.

The metric I've always used for a person if they are thinking about buying mfj is:

If you are a strict appliance operator, if you would send your radio back to the mfgr to repair a defective power cord - don't even consider MFJ. You need the added quality provided by a QC and rework department. You need to pay for those people.

If you don't mind opening up the case or looking around inside your radio, then you might like MFJ. If I have to tighten a bolt or two, or check solder joints, I'm okay with that. I'm going to crack the case on anything I get anyhow.

And how do you beat the warranty? My 259 antenna analyzer quit. I sent it back and they sent me a new one. All I had to do was tell them I was sending it.

I agree 100% on the above statement

i mean theres so many types of people in this hobby now days some want a plug and play radio that uses a computer to work some want on hands some like working on there own radios some arent intrested in learning how to me thats why i got into the hobby was to test play with and work on my stuff thats what i enjoy doing if a person just wants to plug and play (talk on) then MFj might not be for you other wise its all good

ive been using MFJ products for years and will continue to enjoy those products for years to come

Ive been doing some house painting this week so I bought an extension handle at Home Depot. Its a colapsable aluminum handle that extends to 18 ft. It was on sale for $39.95. I dont think I could have bought the tubing that cheap. I only saw a couple of the metal poles left all the others were fiberglass.

Jimmie

The majority of antennas used today are (commercial) circularly
polarized
Ham antennas remain in the linear domain (ala the Yagi and similar)
There are many reasons espoused in CP advantages in "point to point"
What is the main advantage hams hold over the more popular circular
polarized antennas in its "skip" type useage versus "point to point" ?

Huh? By "skip", I presume you mean for HF and DX. Numbers are always
nice.

There are CP antennas for HF:
<http://www.bruhns.us/CP_on_HF/CP_on_HF.html>
<www.roke.co.uk/resources/datasheets/locate-sarsen.pdf>
<www.ascsignal.com/images/content/gov_radar/pdfs/TA103.pdf>
<http://www.antennaproducts.com/ht30detail.html>
The main advantage is that they deal with multipath better and don't
have a deep cross polarization null. I've never tried one so I have
no idea how well (or badly) they work.

For what it's worth, we did some experimentation with CP on 146MHz
repeaters in the 1970's. The results were an impressive reduction in
"picket fence" type of fading for mobiles. However, the anenna gain
was less than an equivalent size linear array, so there was some range
reduction.

1147. Re: Circular versus linear polarization

Newsgroup: rec.radio.amateur.antenna
Date: 2009-08-10 11:29:03 UTC
From: Bob Bob <bob3bob3@suddenlink.net>
Message-ID: <jtc5l6-6dt.ln1@p400bob.personal.cox.net>
Source record: 13909

Jeff/Art

Keep in mind too that cross polarized (circular) point to point links
(ie with a CP ant at each end) suffer from odd reflection attenuation
(ie the polarization sense gets reversed by reflection)

In 70cm UHF experiments I did back in the 80's I found out that a
horiz-horiz system (base to mobile) outperformed a circular-circular by
at least 12dB when moving. This wasnt actually the base reason for the
experiments so I didnt make accurate measurements.

OT Art, but I hope interesting.

How random is the propogated linear antenna HF wave polarization and
does it vary much with single hop and/or high angle? That might be a
starting point for determining how useful CP on HF might be.

Tnxs for the link Jeff.

Hi to all,

NEC gives the pattern for an antenna mounted at a certain height above
an infinite flat ground.

But suppose that we are on a mountain top (summit) with a relatively
steep grade. Does the pattern changes, i,e. is the TO angle going
lower above an horizontal line coming from the antenna?

If so, is there a kind of 'correcting factor' giving the modified
height applicable?

I have bought MFJ products through retailers in the UK and direct from MFJ in the States. The products do what they claim and are generally cheaper and a lot less hassle than building it myself. MFJ seem to be quite happy for customers to poke around inside the cases of their equipment and tightening up the odd screw or rectifying a small fault is all part of the amateur radio learning experience.

In my phone conversations with the factory I have always found them to be very polite, helpful and professional.

I would recommend their products with the proviso that they are built to a price point and you do need a certain level of knowledge to get the best out of their products. I particularly like their range of manually tuned ATU's and the antenna analysers. Pick an ATU with higher power handling if you are going to operate close to the upper limits of any of their models and you should be fine.

Regards

Mike G0ULI

That probably isn't true for VHF/UHF. Take a look at the website of a major supplier of professional antennas such as http://www.amphenol-jaybeam.com/base-station-antennas-search.php. Entering CP in their search engine for base-station antennas yielded 2 results wheras entering VP yielded 365!

One of the reasons for greater use of linear polarisations in professional applications is frequency re-use on the orthogonal polarisation some distance away - i.e. the value of the limited VHF/UHF spectrum. That's certainly true in Europe.

> Ham antennas remain in the linear domain (ala the Yagi and similar)
> There are many reasons espoused in CP advantages in "point to point"
> What is the main advantage hams hold over the more popular circular

Extensive use is made of 'mixed polarisation' for transmitting VHF FM broadcast services in Europe. It may not be pure circular but it contains significant vertically- and horizontally-polarised components. The mobile and portable receiving antennas have whatever polarisation they end up with, more or less by accident, and fixed rooftop antennas are usually linearly polarised. DAB and terrestrial television are transmitted using V or H linear polarisation.

Well, there's nothing like ground truth, JB, so I'll defer to your experience vs my conjecture. Possibilities for further RF attenuation might be the materials in use. Those little rocks used for color and grip. Fiberglass is used a lot for the base, but there may be other fabrics too. It's a composite material, who knows, there might be carbon in it as well.

Hmm A bit too technical for me! When I model my antennas it
shows gain for cp being 3 db above the gains of vertical and
horizontal for the same antenna. Is that what you call "mixed
polarization? In other words, it picks up all polarizations with a
max deviation in signal strength of only 3 db.
I find it hard to make any sort of comparison when using reflective
waves at HF because it is not clear to me exactly what sort of
rotations occur at the reflections on earth and of its layers
together with possible rotation in transit in between in the absence
of true comparison experiments.

Off subject I know but as a matter of interest what happens to a TX CP
antenna with a clockwise twist transmitting to a RX CP antenna with an
anticlockwise twist, over short to medium vhf/uhf paths, I would have
thought a reduction in signal ?

Depends on wavelength vs. distance to nearest ground vs. angle of that
distance.

All things about the pattern are related to phase/time/distance.

About the same as going from a horizontal to a vertical antenna. You loose
about 20 db of signal.
One thing a CP signal will do that a horizontal or vertical signal won't is
to reverse when it bounces off an object. That is if you are doing moon
bounce and send up a signal using right hand CP , your receiving antenna
will need to be left hand CP or you loose lots of db of signal.

Also on the satellites it is helpful to be able to change the CP from left
to right as the signal sometimes reverses depending on the angle the
satellite antenna is pointing as it passes over.

On Aug 10, 8:23 am, Art Unwin <ArthurUn...@gmail.com> wrote:

>
> What stands out for me is the audio improvement.

Only very high Q antennas should noticeably effect audio.
Comparing a dipole to say a turnstile, you should notice
no real difference at all.
I've used turnstiles on 75 and 40 meters for years.
They work very well, but audio improvement is not
one of the usual features noted.
I prefer a turnstile over a dipole on the low bands
if I have my choice.
They seem slightly more efficient overall, but I've
never done any accurate testing. They also tend
to fill in the nulls off the ends that a dipole can show.
I've heard that running a circular polarized antenna
like the turnstile on HF, only shows circular polarization
at the higher angles. Which is what I'm usually using
when working NVIS on the lower bands.

That's one of the big advantages of CP for point to point links. The
polarization reversal on odd numbered reflections means that multipath
is greatly reduced.

>In 70cm UHF experiments I did back in the 80's I found out that a

The book "Microwave Mobile Communications" by Willaim C. Jakes Jr
(1974) has a few words on the subject. As I recall, Ma Bell concluded
that neither linear or cirucular polarization is good enough and that
some form of diversity is required.

Incidentally, "The Practical Handbook of Amateur Radio FM and
Repeaters" (1981) (Tab 1212) by Pasternak and Morris, has chapter 31
on CP tests on the WA6VQP repeater on Loop Mtn. They draw a polar
plot of the measured repeater antenna pattern and note that they get
the typical "flower" pattern, with attendent deep nulls with linear
polarization. With CP, the nulls are far less pronounced.

My tinkering in the 1970's was specifically to reduce severe multipath
fades along a section of freeway in Smog Angeles. It worked, but with
some loss in signal stength from mismatched linear and CP
(theoretically -3dB).

>OT Art, but I hope interesting.
>

I did some tinkering with measuring the polarization of skywave
signals using a rotating loop antenna. Including Faraday rotation, my
guess(tm) is that it's quite random and changes rapidly.

See:
<http://www.cplus.org/rmw/english1.html>
Locate the antenna exactly on the terrain model (SRTM2) and you'll get
the real antenna pattern. You can input the actual antenna pattern
into Radio-Mobile for better accuracy instead of using generic omni,
cardioid, yagi, etc patterns.

Bad examples (but all I have online):

I have though that also, but I have noticed that on 75 meters there
sometimes seems to be a differance in the voice of the other station when I
switch from my off center fed antenna at 50 feet and a dipole at 20 feet.
This is when signals are around the same on either antanna. Around the s-9
point. I am using an Icom 746pro and an external switch to change the
antennas.

I also did some experiments in the early '70s to see if CP would reduce fading. I built a couple of types of omnidirectional CP antennas -- a "skew planar", and a copy of a commercial FM BC antenna, for mobile use with the local 450 MHz repeater. I soon discovered that as soon as I placed the antenna over the top of the car, the polarization became nearly linear. I've since learned that it's because of the nature of the reflections from the ground plane, and it's easily seen with EZNEC+. When I put the antenna far enough away from the car to minimize reflections, the lowered gain offset any possible advantage. Overall, they worked out worse than a conventional vertically polarized antenna. It might have been interesting to try CP at the repeater, but that was never done.

The problem with ground reflection ruining the circularity makes it very difficult to achieve circular polarization for HF skip communication. A second problem is that the majority of CP antennas, such as the quadrature fed crossed dipole "turnstile", are circular only directly broadside, and increasingly elliptical as you move away from that direction.

> could be wrong.

Attenuation isn't a real concern, except when it's raining or the roof
is wet.

What should be a concern is the following:

1) weird interactions between antenna and conductive stuff in the attic.
Don't expect the same feedpoint impedance vs frequency you get with
the antenna out in the open.

2) Fire: The voltage gets pretty high at the ends of a dipole when
you're radiating even 100W. Or, more to the point, the voltage gets
high in nearby wires that happen to be the "wrong" length. A small
ember smoldering in your attic is a huge problem. This is something you
need to figure out how to check.. keeping the active ends of the dipole
clear of flammable stuff is straightforward, but the accidental
excitation of something else, isn't. (wiring isn't a problem.. it's
usually connected to something else that shunts the current.. it's
isolated conductors, like plumbing, HVAC ducts, etc. In your situation,
yours is in the crawl space, so you're in good shape.)

3) RF exposure. Do your calculations and make sure you're not cooking
things you shouldn't be.

Except most of these designs don't work well. The problem is that the
2m elements really mess up what you're trying to do on 70.

There are ways to deal with it. One is that you tilt the elements
forward and use them for both bands. Old trick.

Use your own thread to ask for assistance on your question.
Be prepared to answer why you are requesting this personal service .
I asked a question on this thread with respect to the main advantage
for hams that linear
polarization has over CP. I have no resistance to change if it can be
justified. I see
that it can pick up signals that linear antennas cannot hear because
of a 30 db attenuation
where as CP has only a 3 db attenuation!
So what is it on the other side of the coin is what this thread is
posing to those who are familiar with respect to radiators.

Cross polarization can be used to provide isolation for duplex links or
co-channel sharing.

I think that you are looking at it from the wrong point of view. CP does not have 3dB attenuation, but a linearly polarized signal received on a CP antenna will be 3db down (whether that be H, V or slant).

So for amateur use CP is useful in that with another CP station multipath due to reflections will be reduced (reflections taking on the opposite hand CP and thus attenuated). However, if a CP antenna is used to receive H or V you may well not see the full 3dB reduction due to twisting of the polarization on the path. In fact over some paths the signal on a CP antenna will be better than on a linearly polarized antenna due the a greater attenuation due to polarization twisting.

Of course the best of both worlds is to have a crossed yagi with a phase switching box so that you can select CP (both hands) H, V or slant 45 both ways.

Commercially (terrestrially) I don't think that CP is used much except perhaps on microwave point to point links.

Jeff

Jeff, I want the" best of both" worlds but before one jumps one needs
to know the advantages and disadvantages of both first. To be frank, I
do not know what happens to all signals when they are reflected
including the reflection off the ground to a receiver or a direct hit
on the receiver from our upper layers so I have no way of undertaking
a comparison. Now most hams are resistant to change or will only
follow the majoratory thus the questions "who has the majoratory". For
me I see CP as an ideal approach for smaller volume antennas which is
the "holy grail" for hams, but one has to determine if smaller is
important enough to overide possible faults.Now I have a whip antenna
(no ground plane) on my tower that is CP for top band but the bands
are poor it is difficult to determine its worth especially since
there are no similar radiators out there. So I fall back and ask for
"what is known already" as there is no point in re inventing the
wheel. Is that so bad?
Now before the catwalling about the possibility of having a whip (a 5
foot pole) for top band
my intention is to release all that during the next month. So lets not
waste energy in side tracking comments and stay on the essence of this
thread. Remember the last time I intended to release it was evident
that most did not want to hear it........ so I went along !

A "halo" type of antenna? Some of the commercial broadcast FM
antennas are eliptical polarized. Most of the signal is horizontally
polarized, but there is a small vertical component in order to improve
performance in vehicles.

We tried several antennas at the repeater end. Something like this
one seemed to work best:
<http://iris.nyit.edu/~sblank/VPFMfig5.gif>
We had 4 elements with a coax cable phasing mess.

>I soon discovered that as soon as I

I tried to use CP on both ends and eventually gave up. Thanks for the
explanation, but I have a different theory. The polarization changes
sense (direction) every times it's reflected. We standardized on RH
CP. When the RH CP signal hits the car, it is reflected as LH CP. If
the LH CP signal arrives at the repeater antenna, which is RH
polarized, they cancel. If it became linear, it would theoretically
only present a -3dB polarization loss, which is not huge.

>It might have been interesting to try CP at the repeater, but that was
>never done.

I can testify that it worked quite well for solving the specific
problem. We were trying to eliminate picket fencing (frequency
selective fading or Rayleigh fading). While there were some half
hearted experiments with various CP mobile antennas, the major effort
was at the repeater end. This was about 1971 so the technology used
was rather crude. One student was doing his senior project (reqd for
graduation) around this test. Several of us were enlisted to help.
When was in the land mobile radio biz many years later, I repeated the
tests with similar results.

We hung a thermal chart recorder onto the first limiter testpoint (on
a Motorola Sensicon T43 receiver) and plotted signal strength versus
time as a mobile drove through the problem area with the xmitter keyed
continuously. The test was repeated with various tower mounted
antennas. The linear antenna had more signal (gain) than CP, but also
had many more fades, what were far more pronounced. In all, I would
call it an improvement in quality, but not in range.

>The problem with ground reflection ruining the circularity makes it very
>difficult to achieve circular polarization for HF skip communication.

Well, I supplied several examples of commercial HF antennas that are
circularly polarized. I'm tempted to try building one, just to see
what works or breaks.

>A second problem is that the majority of CP antennas, such as the
>quadrature fed crossed dipole "turnstile", are circular only directly

That's why high accuracy GPS antennas use choke rings at the antenna.
It widens the pattern so that it picks up more of the sky, but also
maintains some semblence of CP at the horizon.

Any interest in me scanning and posting the chapter on circular
polarization repeater antennas from the TAB book? 13 pages with some
low quality pictures.

>
>I am all ears. Go for it

Applied CP made simple:

1. Circular polarization is like a drill. Instead of bouncing off
the ionosphere, it drills right through it. Therefore, little or no
skip with CP.

2. Circular polarization is sensitive to the direction of rotation.
If you're sending CP with your right hand, or using a microphone in
your right hand, then you can only hear right hand circular
polarization.

3. CP changes sense every times it bounces off something. Therefore,
you can only hear even numbered bounces with the same sense. Odd
bounces disappear meaning you can hear short skip signals (NVIS), and
long path, but nothing in between.

4. Right hand CP is the most common, because most tuning screws use a
right hand thread. If you want to use left hand CP, you'll need to
find some rather scarce left hand threaded coil forms and tuning
slugs.

I hope this helps.

You need to read up on it. It does have it's uses and I know hams that use it. Usually by Satellite guys that talk to mobiles too. It gets used by quite a few commercial broadcast FM stations. The theory is that a mobile antenna will hear either the main path or reflected path but to a lesser extent, both so multi-path distortion is minimized. Typically the reflection cause a reversal of polarization. There is no substitute for talking to the far station in whatever polarity is agreed on.

The "skew planar" looked like a cloverleaf antenna with each "petal"
rotated 45 degrees. The other was a copy of a broadcast antenna
advertised to be circularly polarized. I used a simple hand held dipole
and field strength meter to judge polarization. I know now it was
subject to a number of shortcomings, but I feel it did a reasonable job
of indicating circularity. Both antennas were reasonably circular.

No, that's a common misconception. A circularly polarized wave produces
a circularly polarized wave of the opposite handedness only when
reflected from a plane normal to its direction of propagation. That's
seldom the case in a communication environment. When reflected from
surfaces at other angles, the result is a change in circularity, from
elliptical to nearly linear depending on the angle of reflection and the
reflection coefficients of the surface. A short while with the modeling
program of your choice will confirm this.

I wasn't aware of any GPS receivers using crossed dipole "turnstile"
type antennas. All the ones I've seen use either quadrifilar helix or
patch antennas. Can you point to a reference or two regarding the choke
rings -- I don't know what these are or what they do, and would like to
learn.

You bet that they have to read up on it.
For those who consider themselves experts and others idiots.
There is some sort of federation for antenna builders and the
President of that group states we will have a disaster on our hands if
we do not come up with a new technology for what is required in 5
years. Apparently cell phones will be divided into three bands and the
big boys want access to all. This means that they need three separate
antennas on the cell phone to cater for all (his words). They don't
like that idea because it means three antennas in close proximation to
each other. The response to that challenge is to group together the
research facilities to find a "new" technology if ever there is one. A
lot of money at stake and it is for any of you that are knowledgable
in the field to apply for.
Those who are really "knowledgable" already know there is no "new"
technology only the one that they use and they all have researched it
to death such that all the answers have been unfolded to them. It is
also too late to ask God to be a bit more fair and provides some
different options to what we already have.
All I ask of them is to share with the rest of us exactly what
happens to CP when it collides with anything in transit to a receiver.

Describe the circular antenna you are modeling? With the gain you are claiming it doesnt seem to be an apples to apples comparison. I suspect you are comparing a fullwave loop to a halfwave dipole. Show the data you are using for your model or be prepared for most to suspect you of the usual handwaving.

Jimmie.

Roy/Jeff

This is all interesting stuff that I have always wanted to experiment on some more. I note the comment (was it Roy?) about the positioning of a CP antenna over a vehicle roof and the effect that had on the total signal polarization. I slapped my forehead on that one! (ie I should have known and tested for it)

I also used a skew planar loop. It was I guess maybe 400mm above the vehicle roof. It had 4 loops in phase. The halo/3 leaf HP (clover) was the same basic construction. At the time the results of H vs V really astounded me. In my case OTH UHF performance was maybe 12db "better" mainly from the reduction in flutter.

Yes of course! (slaps forehead again!)

This is something that has come out recently in some experiments I have been doing with mobile data comms on VHF SSB. I have a badly written and incomplete page;

http://pages.suddenlink.net/vk2yqa

Before getting into the data side of it I had noted that a lot of intelligence could be gleaned by looking at the Doppler effect from the moving vehicle. Only a tiny 30Hz or so was noted on 144MHz but it showed to my mind that a lot of signal comes from multiplathing and even some comes from double reflections. The level of shift over the Doppler "bandwidth" also showed that it was fairly evenly distributed. ie reflections off plane objects like oncoming vehicles were not really any stronger than from other directions. Such things as large oil tanks though are quite obvious when I correlate the trip timing with nearby objects. This also bought sense to the experiments I did back in the 80's where I tried a 3 el quad on the vehicle with dissappointing results.

So where is this going? I wonder what the result would be Doppler "bandpass" wise if I used a CP antenna on the vehicle and base now? (The above mentioned results are all VP) Given the sense change reflections I wonder if I would get a "null" in the received bandpass due to movement.

I am trying to visualize the result of this;

http://pages.suddenlink.net/vk2yqa/img1.png

during that test. Would I get a series of bands parallel to the envelope edges that would further indicate direction of travel relative to the base. I realize that the direct path already gives that info, just trying to get the likely scenbario in my head.

Apologies to Art for taking his post so far OT.

Cheers Bob VK2YQA

The 300 watt versa tuner utilized an inductor selector switch which had too low voltage rating. I have recently repaired one for a friend to replace the switch. This was a design flaw, and not a QC problem.

I have had an MFJ 259B for 10 years and have about worn it out. Had to replace the coax connector, and the on-off switch, but it keeps on truckin. It did not suffer from a QC problem.

As for the other products you mention, I have no experience. I have bought a number of other products, and all I can say is you get what you pay for.

Do you ever get to the point that your signal bounces off the upper
layers instead of passing thru? I note that some users of the vhf have
seen ducting effects (temp inversions?)

>>> broadside, and increasingly elliptical as you move away from that direction.

Sorry, my original reply to this comment was screwed up thanks to me
talking on the phone while writing.

Yeah, the problem with turnstiles CP is at the horizon. At the
horizon, one element of the turnstile would be roughly perpendicular
to me, thus acting as a simple linear dipole. The other crossed
element would be seen from the end, resulting in no radiation in my
direction. So, at the horizon, a turnstile is mostly linear
polarization.

>> That's why high accuracy GPS antennas use choke rings at the antenna.

If you really want a turnstile GPS antenna:
<www.arrl.org/tis/info/pdf/0210036.pdf>

As for the choke ring, you've probably seen them in the center of
C-band DBS/TVRO dish antennas.

Links:
<http://www.javad.com/jns/index.html?/jns/technology/Choke%20Ring%20Theory.html>
<http://www.trimble.com/infrastructure/gnss-choke-ring-antenna.aspx?dtID=overview>
<http://www.gpsworld.com/survey/news/trimble-choke-ring-antenna-uses-dorne-and-margolin-di
pole-3620>

More detail:
<www.novatel.com/Documents/Papers/3D_choke_ring.pdf>
If you remove the radome in the center, it's a "pinwheel" antenna,
with which I'm totally unfamiliar. Note the comments on "low
elevation tracking", which is what I was mumbling about for improving
the performance at the horizon. The above article don't show it, but
the choke ring does maintain some semblance of CP near the horizon.

Patent on the dual frequency (L1 and L2 for GPS) choke ring:

1192. Measuring loss of vertical antenna roof counterpoise?

Newsgroup: rec.radio.amateur.antenna
Date: 2009-08-12 01:43:14 UTC
From: TF3KX <kristinn1@gmail.com>
Message-ID: <0327ab84-193e-4305-976b-eda4b7dc1272@g10g2000yqh.googlegroups.com>
Source record: 13954

I have erected various vertical and wire antennas from my roof, using its metallic surface as a counterpoise (approx. 10x10m or 30x30ft). I have come to suspect that there are some resistive losses in the roof or the connections to it. My question is: Does anyone have a suggestion for how to estimate by measurements the resistive losses of the roof or its connection?

One idea might be erecting a quarter wave vertical for, say, 20m, and measure the feed resistance. If modeling would suggest, say, an "ideal" resistance of 35 Ohms, but the measured feed resistance would be 45 Ohms, I could conclude that the extra 10 ohms were coming from the resistance at the base, i.e. from the roof or its connections. This assumes that the vertical had otherwise negligible loss (for example, an aluminum tube). Now, to complicate things the roof is sloping (approx. 45 degrees) and the antenna base is located at its peak. This would be hard to model precisely, so that "ideal resistance" would be hard to ascertain, to begin with.

Any other suggestions for estimating the roof connection losses?

I don't know of a good way to do it except modeling. Don't expect 35
ohms, though -- the resistance will depend on the size and shape of the
roof as well as height and diameter of the vertical, and can vary quite
a lot.

I think this one is going to become a portable HF antenna. When fully
extended the electrical connection between sections is not very
reliable so jumpers may be required.\

So the ionosphere knows the difference between CP and linear?

Interesting, since horizontal and vertical both reflect, and CP is a
combination of both.

Could you please explain what's happening with CP?

Thanks.

>program of your choice will confirm this.

With my limited abilities, it will probably take more than a "short while" with an antenna modeling program. I've never done any polarization studies. I'll take your word for this, but it would seem that there would be a gradual transition from total reversal in sense from a perpendicular reflector, to conversion to linear polarization with shallow reflection angles. I'll see if I can find some research on this. (I'm curious).

I once did some crude experimentation on the degree of isolation provided by a reflective sense reversal. I just happen to have two big 2.4Ghz helical antennas, both RH CP. I separated them by about 15 meters and measured the received signal level. I then placed an obstruction (corner of building) along the line of sight, and supplied a flat plate reflector. I didn't think to try varying angles of incidence and reflection and just ran it at 45 degrees from the plane of the flat plate reflector. The signal dropped about -15dB which I guess is about all I could expect in an uncontrolled environment. The loss would indicate that the signal was still substantially circularly polarized at 45 degrees. I still have the helix antennas and can repeat the test if necessary (and if I can find the time).

Thanks for the clarification.

For high performance GPS receivers and measurements, it's important that the apparent position of the antenna be be independent of the look angle to the various satellites. Partly this is by making antennas with a phase center that is look angle independent, partly this is by making sure you're not receiving a combination of direct and reflected waves.

Remember that for precision GPS, what you're looking at is essentially the carrier phase within a single chip time (about 100ns). The carrier phase outside the correlator's time window doesn't contribute to the observable measurement (because it's got a random 180 degree phase shift superimposed on it).

So what you're really worried about is interference that causes an apparent change in phase of the carrier (at 1.5GHz.. call it 20cm wavelength). In precision GPS, you're talking millimeter scale measurements, or, say, better than 1 degree of apparent phase shift. A reflected signal that is 35 dB down is enough to get this sort of error.

The multipath from "distant" reflectors is fairly easily dealt with by putting the antenna on a pole. Distant, here, means a few meters away.. farther than that, and the multipath signal's code phase is far enough away that it doesn't contribute to the measurement. The chip length is about 100 ns, or 30 meters. So, putting the antenna on a pole a few meters up, with a plate underneath it that cuts off the "view" of the ground closer than a few meters away guarantees that you won't see any reflections from something closer than 20 meters path length different.

You also choose an antenna that has very little gain below several degrees above the horizon.

But, just any old flat plate won't work, because you can have a creeping wave propagate across the surface AND you don't want the plate itself to reflect a signal. Solution: make a plate that is a RF "black hole" at the frequency of interest.. it's a series of grooves that are carefully

designed to attenuate the reflected and evanescent wave propagating
across the surface (just like in a corrugated horn).

The most common design is by Dorne and Margolin, and I guarantee you've
seen these if you've seen surveyors doing GPS measurements. They're
about 2' in diameter with several wide grooves around a small conical or
hemispherical radome covering the actual antenna. Sometimes, the whole
thing is covered by a hemispherical radome.

http://facility.unavco.org/project_support/permanent/equipment/antennas/antennas.html

Is a photo of a typical geodetic installation (sub-mm accuracies)

http://www.trimble.com/infrastructure/gnss-choke-ring-antenna.aspx?dtID=overview

is the actual antenna.

> BTW, sending an e-mail to MFJ's support desk is like transmitting
> into a dummy load.

I have an MFJ-9020 20m CW transceiver I bought around 1994 or 1995. I also have a 40m one too. I noticed that the 40m was much better at receiving.

At one time I needed a manual for it, having lost the one I got with it when I moved, and filled out an olnline "manual request form". They sent one to me via airmail.

I was able to align it with the instructions in the manual, but was not able to determine the problem using the voltage measurements, substituting IC's, etc.

I sent them a detailed question via their support form (not an email) and received a helpful reply from the person who designed the rigs.

I know who it was because he referred to other rigs he had designed.

Considering that I bought the rig 13-14 years, I think that's good support.

In the end, if anyone ever reads this in an archive, I found that I got a lot more gain out of it by upping the internal voltage regulator to 10.7-10.8 volts instead of 10. I'm not sure in a high signal environment you would need it, here there are a lot less signals, and they are much weaker.

The cost of doing so is that the radio will now no longer work properly with less than 12 volts DC input. With the regulator set to 10 volts it will work down to about 11.2 volts.

I hate it when I find a post where someone says "I found the answer to" and never says what the answer was. :-)

Geoff.

> Jimmie

You are right.. there's no electrical connection between segments, and no way to simply jumper it (if you put some sort of connector, it doesn't telescope nicely).

However, what you CAN do is support a piece of wire from the top of the pole down to the ground next to the pole, and that works pretty well.

Another convenient and inexpensive support is a collapsible crappie or panfish pole. Cabela's has 20 ft collapsible rods for under $20 (or did a year or two ago).

The challenge with all these sorts of schemes is holding the pole upright. For a "no wind" situation, an orange traffic cone works fairly well. You shove the pole into the hole in the top.

If you need to tolerate even a small breeze, you need something more.

You can also use multiple painter or swimming pool poles (which are sturdier) to make a giant tripod. The handles from inexpensive paint rollers make the appropriate threaded socket for the male thread on the paint poles.

I have used adhesive foil for years on fishing poles.
Ideal for a back pack, un assembled and with foil at the ready!
Last time I saw them on Ebay was $10

In my case, it's too much sense of humor. Answering questions with
accurate information is easy. Just Google the question, excavate
through the resultant debris field, and pontificate on what is found.
A dash of authority and a hint of arrogance provides a defensible
packaged answer. A few URL's are always useful.

However, that's too easy, no fun, and most important, can be done by
any mortal. What's more interesting is to supply a series of wrong
answers. In order to do that, one must know both the right answers,
how things really work, and enough about the problem to be able to
successfully misinterpret any data, phenomenon, and physics. That
requires considerably more skill than merely knowing or finding the
right answer. What looks like humor, is really an intellectual
exercise.

Note that supplying wrong answers is not limited to technical Usenet
newsgroups. Lawyers do it while presenting evidence to give the jury
a misleading packaged interpretation of the evidence.

There's also an educational benefit from providing wrong answers. If
one knows all the wrong answers, whatever is left, no matter how
complex or irrational, must be the right answer. Therefore, if you
study how thing do NOT work, you will have a default understanding of
how things actually do work.

I thought it sounded like a good setup, but I checked the internet and found the URL below. Maybe it would help to spread a few ground wires out from the base of the antenna to be sure of the counterpoise effect. I have an SUV with one of the antennas in the middle of the roof. When talking to local operators they tell me they can see the difference in signal when the vehicle is pointed away or toward them. Must be a good counterpoise off the roof.....

Perhaps a bit out of norm for this group, but I am trying to find a source for VHF and UHF isolators that are somewhat less than the normal exhorbitant price of many public safety communications equipment providers.

Any leads appreciated.

> I thought he said earlirer that it had a 3 db gain

When I modeled my antenna the max gain was CP I then checked for
linear gains
on the same set up and they were 3 db down. I suppose I should have
set it up for max linear gain and then checked CP gain on the same set
up. (Made a note to myself for future). For end fed antenna, the gain
max was around 13 dbi but 10 dbi seemed to be more the norm. What
really pleased me was the near 50 ohm impedance feed.
The biggest advantage is that people with small yards will now have no
problems on getting on top band with directional antenna and be able
to use the whole band! However, regardless on the ideas I have checked
out on it I am very confident that hams will immediately will be able
to improve it in ways I have not thought of. As with all thoughts
others will say I knew that but I couldn't be bothered because once
the dots are connected
everything appears to be obvious. A jigsaw puzzle with all the parts
turned over is tremendously hard to solve. Once you have seen the
picture it is a different ball game.
The antenna is extremely quiet, and as I have mentioned before the
audio quality is such that I immediately look at the meter only to see
it on the low side. Perhaps the CP pickup
does not register the same as for linear. It is my hope that all will
tackle building one this fall
so that the improvement horizon will broaden while I am still around.

Another option at a similar price (and less when it's on sale) is
Harbor Freight's 3-section telescoping flagpole. It's three aluminum
sections, 16 feet (1/4 wave on 20 meters) when extended. Their stock
number is 92901-8VGA.

Cheers,
Tom

You stated that MOST commercial antennas are CP. Having been in that
business to some extent, I know that statement to be false. I'm simple
asking you to prove it.

Also where is this information that shows linear antennas have 30dB of
attenuation? When? How? What conditions?

And when do the CP antennas have 3dB by comparison? Give references.

I know you can't since all these things are figments of your addled brain.

If you are horizontally polarized a vertical will be down 30db
theoretically than if it was horizontal and vica versa. If the
radiator is set for CP transmissions other polarizations
will be down only 3 db theoretically. Seems obvious which is best to
have, except a lot of hams like long distance communication which
means you have to deal with reflections.
From this thread it is obvious to me that we are not sure, at this
point, what changes occur
when reflection comes about. Roy pointed out a "misconception" at
least to his findings but the fact is there is no list of known
changes that one can bank on for reflections of CP at least for the
present. If I am incorrect then please post your thoughts.

No, I am not Tom you are just extending your mouth. Obviously those who give me a hard time don't get to share. There are others who do not give me a hard time who get to share.
If you are an outsider to every thing then I understand why you lean on the term "ridiculous"
Remember the discussion on Gauss? You never did reverse your position which is against classical physics so you are an unproven quantity to most with respect to antennas and radiation.
You could, ofcourse, provide a list of polarity changes upon collision instead of your dart throwing which is never accurate. Why don't you plonk me or are you just a nasty person?
Maybe you can start a separate thread for just you and me so you can sound off, insult and have a good time.

I never expressed any opinion on Gauss. More of your mid slips.

> You could, ofcourse, provide a list of polarity changes upon collision

What polarity changes? I have not been in the discussion about CP
reflections, just the claims you made about CP antennas being dominant
in the commercial market, which they are not.

> instead of your dart throwing which is never accurate. Why don't you
> plonk me or are you just a nasty person?

I only throw darts at targets, and you give many.

> Maybe you can start a separate thread for just you and me so you can

Hello,

googling about "underground antenna", i found this article:
http://www.caves.org/section/commelect/nec-4/nec-4.html
that talk about a version of NEC capable to modeling under-the-ground wires.
IIRC also Roy W7EL write down months ago something about this, and about the
why the NEC capable of this kind of modeling (buried wires and so on) is not
released to the general public. Roy, if you gently can re-explain to me this
i'll be grateful.

Just for my personal information, wondering if someone played with buried or
submersed antennas and (especially from 40 meters going lower in frequency)
get some interesting result.

Thanks for reading and for replies, and as usual sry for my poor english.

NEC-4 is capable of modeling buried wires, and NEC-4 is available to the public. For information about purchasing NEC-4 see https://ipo.llnl.gov/?q=technologies-software-browse_software-app&s=NEC.

Where do you get 30dB from? 'Theoretically', it ought to be infinitely
down. In practice, because of reflections and things like that, it can
vary from 'a bit down' to 'a hell of a lot down'.

>If the
>radiator is set for CP transmissions other polarizations

This is correct. You are splitting the transmitter power - half power to
each orthogonal polarisation and, with a 90 degree phase shift,
producing a circularly polarised signal (instead of a 45 degree slant).

Correct.
A reference supplied earlier by Jeff in this thread stated "real
world
20db to 35 db" (You used the term "in practice) A manufacturer used
the figure 30 db when I followed thru on his other references which
also appeared to me as being reasonable

For frequencies below 50 Mhz. you can't get enough counterpoise. Yes it
does matter which way you are facing because you probably can't get decent
symmetry below 144 Mhz either. Center of the roof helps but you will be
operating at rest, a bumper mount will at least do better somewhere. I have
a metal roof and it does change the loading from the typical ground mount,
but is an improvement. For a while I operated from the shack with 40' of RG
8 out to the truck with Hamsticks.

Hi there,
I noticed at one point a reference to displacement current
where ..... " in this case it cannot be ignored!" Where and why in
modeling would one ignore displacement current when it is part and
parcel of Maxwell's laws?
Many thanks

The REAL Question here is how are the Roofing Material Sheets bonded
together, both physically and electrically?

I have a Galvanized Steel Roof on my Cabin, where each sheet is spot
welded to it's neighbor in four places along the common length. This
provides a very effective RF Ground for a 4BTV mounted in the center on
the peak. clear down to 2006 Khz, with an applicable Tuner. I also have
a 130 Ft End-feed Longwire that uses the same Roof, via a SEA330
Autotuner for 2.0-22 Mhz Marine Operations. I have install a lot of
these type systems around Alaska for Fixed Comm's Systems over the last
3 Decades, and most are still in use even today. The bonding and
connections between the panels is the critical point for this type of
system, and Self-Tapping Sheet-metal Screws, just don't cut it in the RF
World. It isn't hard to do when installing the Roofing material in the
first place, but it IS hard to retrofit once the roofing is in place.

I like the whole part of the form where I had to certify that I wasn't doing nuclear weapons design, nor was I planning on using NEC4 for the design, development, production, stockpiling, or use of chemical or biological weapons.

They apparently don't care if I do those things, I just might not be able to use NEC4 in the process.

Hi Daniel, If you are new to antenna building, I would start with
something simplier, say a single band 2 element quad with a boom, or
if you are good at welding and metal fabrication, a single band Spyder
quad. Usually they are D.E. and Reflector.

A 3 element multi band Spyder quad is quite an undertaking both in terms of building, and getting it to work satisfactorily on all bands, not for a beginner.

The only important thing is that you *say* you're not doing those things. We all know that nuclear, chemical and biological weapons developers would never lie about what they're doing.

But this is a big step beyond how things used to be. Until a few years ago, NEC-4 could be sold only to people who said they were U.S. citizens for use in the U.S. So it was trivial for any potential enemy to get the program which could be carried anywhere in the world on a floppy disk in a shirt pocket, or even sent by email. In the meantime, users in friendly countries had to apply for an exemption via diplomatic channels. I know of at least one case where this was done, and approval took several years.

Daniel,

I agree with Gary - building and tuning a quad properly is a lot of work, and perhaps it is better to start with a smaller, 2 element quad and improve it later?

My antenna is made by Gem www.gemquad.com , which is a boomless design that offers optimal spacing on all bands. If you are good at welding and can build the center spider support, the rest of the antenna is easier. My antenna began as a 3 band (10, 15, 20) model, then added loops for the 12 and 17 meter WARC bands. Then I added a 2 element 30 meter "U" shaped dipole beam between the 20 and 17 meter loops. Then I added a D.E. and reflector for 6 meters. So, although it is only a 2 element quad, is it is now a 7 band antenna!

I use a remote antenna selector switch on the mast of my quad, and select the bands in 4 groups: 20 meters alone, 30 meters alone, 17 and 15 tied together, 12 and 10 meters tied together, and 6 meters. Because the base impedance of a loop calculates at 105 ohms, I use a 1/4 wavelength 75 ohm feedline in each group of wires to bring the SWR to 1:1 for each band. (The 15/17 group feedline is cut for 15 meters; the 10/12 meter group feedline is cut for 10 meters. SWR is still excellent on the 17 & 12 meter bands.)

My quad has been in the air for 9 years and gives me very good performance, but I must tell you that an antenna with this much wire at 70 feet requires a LOT of maintenance. This quad is mounted on a tilt-over tower which makes fixing the antenna easier -- I can drop the tower with a motorized winch and work on the antenna from the ground. I would not recommend that anyone install a quad on a stationary tower that requires adjusting/repairing at the top of the tower.

I hope you find my information helpful. Please feel free to email for more information.

Thank you Larry and Gary for the precious information. I will turn into a 2 el. quad as I understand the difficulties for a beginner.
Your comments have been of great benefit.

Good DX

I have one, and to me it seems reasonably well made and more rugged
than the telescoping pole I have for window cleaning that's probably
similar to the Home Depot item you originally posted about. I would
recommend planning on some sort of strap between sections, to assure a
good RF path. They also have a 4 section, 20 foot one, though it's
over 50% more expensive.

Cheers,
Tom

1244. Aluminum spreader quad

Newsgroup: rec.radio.amateur.antenna
Date: 2009-08-15 19:11:49 UTC

I was talking with some guys this AM about building a quad antenna using aluminum spreaders. I know that it at least the tips of the spreaders would have to be made of insulating material such a fiberglass but the consensus seemed to be that most of the spreaders should be non-metalic. I was wondering if anyone here had built a quad with almost all of the spreaders made of metal and what was the results.

A few years ago, I had a Hygain 3-band quad with aluminum spreaders.

"Strategically placed" insulating rods divided the spreaders into
non-resonant, neutral segments.

I was thinking about a single band quad. I figured that on a single
band quad the length of the spreader would be either 1.414 or .707
(depending on how you see this) times the lenght of one side of the
quad. I dont think this would be close to being resonant.

I am just waiting for his new contraption that is going to produce
circular polarized waves on 160M and you could haul it in the trunk of
your car. I hope that when I am as old as he says he is that I will
have morre interesting things to do wiith my time than tilt at
antennas.

1249. MFJ-269 Antenna Analyzer experience

Newsgroup: rec.radio.amateur.antenna

Hi all

I'm looking at purchasing an MFJ269 antenna analyser and keen to hear
experience of others in this group regarding this or similar analysers.
Appears to be ideal if it is as good as MFJ claim.

I have one and find it extremely handy for a variety of tasks such as measuring the length or velocity factor of coax lines or the impedance of ferrite cores. But ironically, the one thing it's almost completely useless for, at my QTH, is analyzing antennas. Induced fields from TV, FM, and AM broadcast stations are so high that the MFJ isn't able to detect its own signal. This isn't unique to the MFJ -- I've had the same problem with a very expensive HP digital impedance meter, and revert to my old GR bridge with a tuned receiver for a detector when I want to actually measure an antenna's impedance. For me the MFJ is worthwhile just for the other functions it provides, but it might or might not be for you. Just keep in mind that, depending on your QTH, it might not be able to actually measure antenna impedances.

Roy Lewallen, W7EL

Are the two 0.35WL spreaders shorted together in the center
or are there four 0.175WL spreaders insulated in the center?
Seems to me, this could easily be modeled using EZNEC.
